It is striking how the website of *Museum of the Mind*, just like a number of other publications on Janssen, frames her and her work (*Fantastike, Covida Magazine*). What is emphasized is Janssen’s private method, highlighting a certain intensity and persistence in her research, her affective potential, and her specialness as a person (*Museum of the Mind*). No titles of her works are mentioned, as is usually the case in an online catalogue. Neither is Janssen related to other artists that she may have been inspired by, or to artistic currents she may be compared to or positioned in. All this underlines her status: She is an artist, but a different *kind* of artist. Janssen practices a singular method, produces a singular art, and has not been trained in an official art academy. Such singularity marks her as an outsider artist: Her work is “other” because her affective, embodied experience is “other” (Cardinal, *Outsider Art*). As the online catalogue of *Museum of the Mind* suggests, she creates work untroubled by rules of the game, on the basis of her own intuitions or fascinations, using her own techniques and experience. She is an artist unrelated to the mainstream artworld, even though her work is – or has been – on show in Amsterdam, Havana, and Berlin.

Decades ago, Roger Cardinal coined the term “outsider art” to frame, and thus render visible in the field and study of art, work by artists such as Wies Janssen. Since its introduction, his term has in English come to replace other (and earlier) terms like art brut (Dubuffet). As Cardinal

explains, outsider art is a form of artistic expression that willingly or unwillingly shuns the “public sphere” (“Outsider Art” 1459). It is art that may not necessarily have been produced for commercial gain and/or public recognition. For Cardinal, such art is “other” insofar as it is singular: It “can be highly idiosyncratic and secretive, and reflects the individual creator’s attempt to construct a coherent, albeit strange, private world” (1459). The problem with this delineation of outsider art, in the context of the strange and private, is that its appreciation hinges on (what Eve Kosofsky Sedgwick calls) the presence of lack (Sedgwick): on a doing, thinking, seeing, or feeling “otherwise” that is interesting artistically *for that reason*. For instance, Janssen’s work has been said to “render visible her inner world”: it has value in so far as it reveals otherwise inaccessible experiences (*Covida*). It is art, yet it is exhibited in separate spaces dedicated to works by other artists who are mentally and/or physically divergent and who work from within a more isolated experience. Still, as sculptors like Judith Scott (1943–2005) illustrate, such works need not remain “outside.” Scott’s work characteristically involves wrapping found objects in colored yarns and thread. Her method has profoundly influenced other artists – such as the artist duo Heringa/VanKalsbeek – and has gained worldwide recognition since 1999 (MacGregor, Heringa/Van Kalsbeek). This is when she cast off her outsider status to become a celebrated contemporary artist. If there is “outsider” art, there is also “insider” art. Or rather, “insider” art is the unspoken, invisible norm against which “outsider” art is pitted as an exception. Speaking of “outsider” art is thus implicitly to think in terms of a value hierarchy, of a norm and its other. As fruitful as Cardinal’s concept has been to highlight varieties of artistic production outside of the official art world, it also reinforces a binary (and a mechanism of exclusion) it was meant to redress. Moreover, with its emphasis on isolation, the idea of “outsider” art fails to capture the *social* circumstances that inform the work of “outsider” artists: Their exclusion does not occur in a vacuum, and neither does their training.

Outsider art has in recent years come to include all kinds of artistic forms, rather than only artists

who have had no formal training and work from nonnormative perspectives. Thus, outsider art now also includes pop culture, street art (graffiti), and other forms that – in one way or another – diverge from “official” artistic practice. Significantly, however, while a lot of research has been done on these divergent practices as outsider art, outsider *writing* has never turned into an official concept, or into a robust archival presence. Yet, many writers fit the concept. Writer-painters like the American Henry Darger (1892–1973) easily come to mind, who – largely self-taught and a hospital custodian for the greater part of his adult life – lived with the trauma of years of abuse and maltreatment in the Illinois Asylum for Feeble-Minded Children, from which he eventually escaped. An inventory of his writings, *The Writings of Henry J. Darger: A Catalogue Raisonné and Reader's Guide*, was prepared by John MacGregor and Betsey Wells Farber in 2001 for the Contemporary Center of the American Museum of Folk art (Macgregor). It contains his epic and illuminated manuscript *The Story of the Vivian Girls, in What is Known as the Realms of the Unreal, of the Glandeco-Angelinian War Storm Caused by the Child Slave Rebellion* – which, containing more than 15,000 pages, is reportedly the largest work of fantasy fiction ever written (Yu).

Instead of a writing by neurologically divergent creators only, I would propose that outsider writing, or outsider literature, is a writing beyond a professional field, beyond immediate acclaim, competition, celebrity, and success – whether by choice or by force. Emily Dickinson is a famous example, like William Blake or Franz Kafka, though also an atypical one as outsider writers (like outsider artists) are not that likely to end up in literary canons worldwide. Be that as it may, the difference between outsider and insider writers/writing should ideally not be seen in terms of a binary opposition, but more as a continuum: “outsider” and “insider” are two poles on that continuum with many variations in-between.

These variations could not only include zine- and other forms of life writing (Poletti), prison (life) writing (Elsinore-Bennu Think Tank), and refugee (life) writing (refugeetales.org), but also graphic medicine and writers working from neuro-divergent perspectives, such as Robert Walser and his miniature writings created, in part, during his 25-year stay in mental institutions (Walser) or Babouillec’s *Voyage au centre d’un cerveau d’autiste* (2021), written as the account of an intelligent woman – Héléne Nicholas – unable to communicate her thoughts and ideas to others due to severe autism (Shaw). Yet such an incapacity to communicate may also have other reasons. For one, imaginative thinkers in the global south may not have the means to write (ranging from education to screens, or even pen and paper) so that their imaginative worlds cannot be recorded and published – and the same applies to refugees, indefinitely detained, or those imprisoned for life. Their work, their writing, is not possible as they are barred from certain rights and resources. Artists and writers are disprivileged in all sorts of ways, blocking their entry into professional fields, and as such remaining “outsiders.” This is why I emphasize “by force or choice” in my definition of outsider art and writing as a practice extending beyond what museums, publishers, critics, canons, or other gatekeepers offer. Who gets to occupy a space of creation, who does not? Who gets to be seen or heard? The relevance of the term “outsider art/writing” is, accordingly, to remind us of the dynamic between private and professional fields: a dynamic where art and literature may (not) become possible as alternative and imaginative ways of worldmaking.

The Parable Proxy of Possibilities

Paulina Larocca
University of Technology Sydney, Ultimo,
Australia

Abstract

The Parable Proxy of Possibilities is an innovation framework that enables organizations to safely interrogate the perspectives that materialize and maintain the status quo to generate system-wide transformation. The status quo is a convention that provides the knowledge needed to navigate and sustain culture, creating meaningful relationships that enhance people's emotional and physical well-being (Lakoff and Johnson 2008). However, it also suppresses innovation by stifling perspectives that question its truth. Culture gives society a shared meaning that makes its members feel emotionally centered and secure as it anchors them in the world. Culture creates its narratives with the myths and metaphors that materialize as its objective reality. Without the sense-making of culture, people feel displaced, so they suppress perspectives that can contradict the status quo – their truth. However, the status quo is not a sacred state. It is a metaphor for a culture's collective agreement of reality that limits knowledge production by excluding other epistemologies. Today, society is in desperate

need of new ways of thinking about the planet's social and climatic challenges. It needs to increase the resilience of the status quo to embrace new knowledge without its members feeling displaced. The Parable Proxy of Possibilities is a framework to help new perspectives be incorporated into the status quo to engender more possibilities. It does this by demonstrating the *similar differences* (Bohm 2004, p. 60) of others' perspectives to enable new relationships to be discerned to enlighten and safely expand the worldview of the status quo. In this light, as the name reflects, the Parable Proxy of Possibilities is a creative insights generator rather than a creative problem-solving process model.

Keywords

Creative insights · Status quo · Imagination · Perspectives · Possibilities · Diversity · Culture · Creative problem-solving · Innovation

The Parable Proxy of Possibilities is an innovation framework designed to help people and organizations materialize and sustain transformational system change. It does this by providing a safe mechanism to re-evaluate its cultural knowledge to shift the center of its status quo. It incorporates tenets from Confucianism, ancient Greek mythology, Celticism, Aboriginal Australianisms and marries it with the status quo to demonstrate the

similar differences of the knowledge systems. By uniting these diverse worldviews into one framework, new relationships can be discerned, providing more ways to work with knowledge. This approach can enrich, enlighten and expand the potential of the status quo.

Creative insights start with the “perceptual discrimination of similar *differences* and *different similarities*” (Bohm 2004, p. 60) to create new relationships that enrich a culture’s understanding of its world. An example is Einstein’s general theory of relativity that altered the course of the status quo. A significant factor in developing his theory was his isolation from academia – he was working at the Swiss Patent Office at the time. This separation from the status quo enabled him to freely combine domain-specific knowledge to discern new relationships (Clark 1973).

Einstein was a trained scientist who pursued a university career after graduation but was never employed. By the time he published his ideas, he had accepted a nonacademic career path. So, there was no longer any social risk in posing a radically new idea as he was not part of the scientific establishment. Einstein was, however, a member of the status quo with his education, promising career, and marriage, so his creativity was a product of his culture (Glăveanu 2010). His patent office training helped him describe complex phenomena with accessible metaphors, which contributed to his ideas catching on. “Einstein’s relativity of time is a reform in semantics, not in metaphysics” (Clark 1973, p. 62). Freedom from academia’s domain-specific ideals enabled him to perceive new, undiscerned relationships and characterize them as *similar differences* (Bohm 2004). After his theory was published, he became a university professor. His ideas were integrated into the status quo creating new knowledge that has exponentially increased the number of possibilities taken for granted today.

Without the creative insight generated by Einstein’s breakthroughs, the world would be greatly impoverished. Diversity should not be a tick box exercise that allows others’ perspectives. The status quo is not structured to hear its perspective and respect how it works with knowledge. As Csikszentmihalyi (1997) said: “We

have repeatedly seen, most creative achievements depend on making connections among disparate domains” (p. 338). However, a culture or domain’s shared language tends to screen out those who do not speak the codes, limiting its potential and stifling its growth. Fortunately, Einstein had not sought the experts in the field’s approval before actualizing his theories. “We shouldn’t turn perspectival worlds from an ontological reality into a normative ideal” (Glăveanu 2020, p. 95). Education and career specialization excludes diversity with its closed knowledge systems. In this way, a culture maintains its status quo. However, limiting possibilities and perspectives also makes organizations susceptible to destabilization. Disruption does not need sanctioning from the status quo to occur.

However, we should not consider Einstein a lone genius operating outside his culture. Instead, his creative insights were a discontinuous break from his culture’s continuity of thought (Weisberg 2006). Situating his creative insights as *similar differences* enabled the status quo to accept his ideas without feeling threatened. By demonstrating the complementary nature of his breakthrough, the status quo’s narrative could incorporate the insights to create new orders of knowledge. “We tend to think of things, not relationships, as the heart of reality. But most often, the opposite is true,” says theoretical physicist Stephon Alexander (as cited in Cole 2019). Respecting and augmenting the current myths and metaphors to create new orders of thought can be a more effective strategy for diversity than replacing one ideology with another’s. It maintains the safety and security of the status quo while stretching what it thinks is possible to create more potential.

Likewise, the Parable Proxy of Possibilities (PPP) does not seek to homogenize or create false harmonies among diverse perspectives as this does not lead to creative insights. Instead, the PPP reveals new relationships by highlighting *similar differences* to lead to new orders of thinking that can safely enlarge the status quo. The PPP also facilitates creative insights to generate discontinuous breaks in the continuity of culture to increase the potential of the status quo. That is

The Parable Proxy of Possibilities, Fig. 1 The Parable Proxy of Possibilities

why Fig. 1: *The Parable Proxy of Possibilities* has a diamond-shaped heart that embodies *all possibilities* while pumping the lifeblood of *respect* throughout its arterial network.

The notion of *respect* is a simple but profoundly deep concept because it does not judge but seeks to understand, and it cannot be separated from the PPP's heart of *all possibilities*. The two are organs of one system because denying another's perspective does not mean it ceases to exist. It just limits its ability to materialize in a way that can benefit the status quo. Using *respect* instead of the more

familiar concept of *deferring judgment* from the Creative Problem Solving (CPS) methodology was deliberate. In CPS, deferring judgment means evaluation is held later to “entertain” (Puccio et al. 2012, p. 51) alternatives that could be novel and useful challenges to the status quo (Puccio et al. 2012; Runco and Jaeger 2012). This approach has its issues by retaining the concept of judgment and enshrining the status quo as the standard to assess the value of new concepts. In doing so, this approach suppresses epistemological knowledge that could enlarge the potential of the status quo.

Instead, the PPP uses the concept of *respect* from an Australian Indigenous Knowledge system, which “accepts that diversity is the basis of creativity and adaptation; therefore, it does not strive to convince others to become the same” (Sheehan 2011, p. 69). The PPP’s lifeblood is *respect* because it embodies freedom from the status quo while maintaining its relationship. It does not subscribe to replacing one ideology with another, reinforcing a win/lose mentality. When that mindset is deployed, losses are characterized as having a greater psychological weight, so people will work harder to avoid them, even if it prevents them from realizing other possibilities that may be better in the long term (Kahneman 2011). “How we imagine the world determines what we think important in it, what we select for our attention” (Samuel and Thompson 2021, p. 13).

The usage of the status quo as a cultural balance sheet has real-world consequences that can create inequity (Buchanan 2004). It reflects what a culture values (and does not), which is treated as truth and materialized accordingly as an objective reality (Lakoff and Johnson 2008). Typically, society treats *its* beliefs as the truth, *yours* as a mistaken conviction, and *theirs* as a myth (Pettigrew 1979).

However, this reliance on the status quo for security promotes short-term thinking as it is not that stable. Just look at the rise of cancel culture and the #metoo movement. Condoned behaviors accepted as an inherent part of an organization’s culture can now make a highly ranked member a social pariah.

Further, power imbalances that are advantageous to the status quo in the short term tend to converge with the “disadvantaged” and “marginalized” over time. As an example, look at the environmental damage caused by industry. In the short term, profits and cheap consumer goods seem more important. However, when a culture embodies the meta-perspective of *respect*, which treats *all possibilities* with reverence, it can see that its interests are much more aligned than it may, at first, realize. Society finds that it cannot destroy someone else’s

environment without damaging its own, with severe ramifications for its health, security, and well-being.

People rely on the status quo for their safety, security, health, and well-being. However, when a culture stifles its growth by not *respecting* another’s epistemology, it hastens its collapse by being willfully blind to the unintended consequences represented by *all possibilities*. *All possibilities* remind people that a social collapse is possible without *respect*, and denying it does not make it less probable. Reality, when it is mistaken for truth, is unstable. “Culture is epistemological because it makes our experience understandable, and makes us feel as if we know our world and our places in it” (Demerath 2002, p. 208).

The continued usage of the status quo as a cultural balance sheet materializes as a resistance to change characterized by winners and losers, decreasing its potential. As Kahneman (2011, p. 305) said:

In human affairs, the same simple rule explains much of what happens when institutions attempt to reform themselves, in “reorganizations” and “restructuring” of companies, and in efforts to rationalize a bureaucracy, simplify the tax code, or reduce medical costs. As initially conceived plans for reform almost always produce many winners and some losers while achieving an overall improvement. If the affected parties have any political influence, however, potential losers will be more active and determined than potential winners; the outcome will be biased in their favor and inevitably more expensive and less effective than initially planned,

When the status quo disrespects others’ perspectives by denying their *similar differences*, it puts its safety in danger. An organization can limit its potential with its inability to respectfully listen to diverse perspectives by inhibiting the generation of creative insights that could enrich it with new orders of knowledge.

However, disrespecting others’ perspectives by not seriously considering their views as a valid truth does not prevent any of the unexpected consequences contained in *all possibilities* from coming to fruition. Just look at the disruption caused by COVID-19, which was not wholly

unpredicted. It was an incredibly destabilizing event with devastating consequences that also demonstrated the fragility of the state of the status quo and the need for greater resiliency.

Disrespecting others' perspectives decreases an organization's resiliency. It cannot assume that its future is continuous from its present. When an organization is rigid in the face of inevitable change, it becomes brittle, not flexible (Aerts et al. 2012). However, organizations fear chaos, so they struggle to embrace the notion of discontinuous change. While healthy systems that embody change and chaos are more resilient and adaptable. "New structures emerge not in changing the state of equilibrium but in the state far from equilibrium. It is the fluctuations that enable a system to move from one state to another" (Aerts et al. 2012, p. 109). Stability, when used in systems thinking, contains a "hidden assumption of linearity, associated with predictability (return to equilibrium state after disturbance)" (p. 112). The original meaning came from the concept of "ultrastability" (p. 108), which means a system is adaptive and flexible to retain its overall structure. A healthy system uses ultrastability to create possibilities by metamorphosing with chaos to make itself more robust.

When an organization labels diverse people as "marginalized" and "disadvantaged," it is disrespectful because these labels act as a proxy for the truth (Lakoff and Johnson 2008). They can also, unintentionally, suggest and permit people so labeled to be treated like that. It is difficult for people classified as marginalized to feel they can share their perspectives perpetuating the issue (Hughes 2016). Likewise, it is hard to hear marginalized voices as their disadvantaged perspective is labeled as different from the status quo.

The more an organization accepts these categorizations like "marginalized" and "disadvantaged" as part of their status quo, the more they become entrenched in that perspective and resistant to contradictory ideas. "The more we know about something, the more gratified we are by reinforcements of that knowledge, and the more upset we are by contradictions" (Demerath 2002, p. 209). This way of thinking leads to a suppression of perspectives

that could enlighten the organization because it seemingly threatens the status quo. These "marginalized" perspectives are cast as different, e.g., dangerous, because their views lack the metaphorical scaffolding that demonstrates their relational similarities. Without this, their perspective is a threat when it could be helping enlighten the organization to create new possibilities. As Kahneman (2011) said, if the "losers" have clout, they will use it to stymie progress – limiting potential.

Society fears diversity because it introduces complexity, conflict, and chaos (Bassett-Jones 2005), while not fully realizing that their metaphorical characterization of events contributes to how they experience it. When they say they are *divided* or *conflicted*, it becomes their reality (Lakoff and Johnson 2008). "The language of argument is not poetic, fanciful, or rhetorical; it is literal. We talk about arguments that way because we conceive of them that way – and act according to the way we conceive of things" (Lakoff and Johnson 2008, p. 5).

However, in Greek mythology, chaos is undifferentiated potential (Wheeler 1995), meaning diversity is part and parcel of harmony. Ancient Greek mythology characterizes chaos as a force *of* nature as in one with it. Similarly, in ancient Chinese philosophy, "a harmonious world must be a diverse world. This is so because a healthy and prosperous world relies on its diverse things to go together" (Li 2006, p. 585). *All possibilities* at the heart of the PPP framework embodies all these epistemologies as related concepts with *similar differences*.

The PPP framework does not seek to solve problems by blending or suppressing epistemologies because it limits possibilities. Instead, it generates creative insights by recognizing that the possible is not in an either/or relationship with the impossible. The two are in a dynamic dance, and the gap widens or narrows depending on the perspective. When the two are closer, it is easier to discern that they are *different-similar* perspectives of the same system. Working respectfully *with* the status quo enables the generation of creative insights to affect transformational system change.

Limitations of the Creative Problem-Solving Process Models

Problem definition, or how an issue is framed, suggests it has a solution and steps to solve it (Bardwell 1991). That is not an issue per se, as all perspectives reveal and hide information (Glăveanu 2020). “Being able to redefine or reframe a problem and to explore the ‘problem space’ can help broaden the range of alternatives and solutions examined” (Bardwell 1991, p. 603). However, categorizing challenges as “problems” and outcomes as “solutions” can obscure its metaphorical use and mythical connotations. It implies that the problem-solver can control their environment and materialize outcomes that fix the system. However, since the system is interconnected, it cannot be changed without altering the whole. These changes will then generate unintended consequences that will be experienced differently depending on one’s perspective. A problem solved, like eliminating environmental waste, is an issue for someone else when it appears in their backyard.

Compounding the problem/solution paradigm’s limitations is that “people tend to solve problems in ways that fit into their preexisting maps; they do what they did before. At its best, this means one has an adequate map for dealing with a new situation. Unfortunately, this also means that ... more effective options are overlooked” (Bardwell 1991, p. 605). The problem/solution paradigm combined with the creativity of the solution being assessed in terms of its novelty and usefulness versus the status quo limits possibilities. It also can create inequities by not considering the consequences of the “solutions” apart from the perspective of the status quo. There will always be unintended consequences. However, that does not mean that an organization can willfully ignore the consequences of its actions on others.

That is why the PPP encourages the embodiment of as many different perspectives as possible. It does this with its use of the Celtic four-leaf clover device, representing the embodiment of knowledge as in Fig. 1: *The Parable Proxy of Possibilities*. The Celtic knot flows in many

directions, even reversing and crossing paths to form a pattern. Like how knowledge flows, as it creates new *meanings* from its *myths* and *metaphors* to *materialize* new realities. The Celtic knot also represents the “boundlessness of the imagination to the order of reality” (Heinz 2008, p. 14).

The PPP creates knowledge bridges between epistemologies by co-creating the flow of boundless imagination to generate new myths and metaphors to enhance the status quo. It creates an embodied experience with the Celtic knot symbolizing a human body. The head is represented by *reflect* and is the mind of culture using *myths* and *metaphors* to conceptualize its world. The left arm reaches into the past to illustrate how a society *relates* to knowledge, how it uses *myths* to create *meaning* it treats as truth. Simultaneously, the right arm reaches for the future to *reveal* what society is becoming with its changing *metaphors* that are *materialized*. The feet *respond* grounded in a *material* reality that has a shared *meaning*. The outermost rings represent the *unknown* forces that influence the system but cannot be detected from the perspective of the status quo.

The realizations gained embodying the PPP will encourage more equitable outcomes. By internalizing another’s perspective, an organization can discern relationships that can help expand its potential. Meaning acknowledging and even privileging another perspective cannot take something from the status quo; it can only add possibilities that enable transformational change. Indeed, more than additive, new perspectives could be multiplicative.

Though a person cannot objectively know what it is like to be another being, “at present we are completely unequipped to think about the subjective character of experience without relying on imagination” (Nagel 1974, p. 449). Organizations still have an ethical obligation to try.

The PPP recognizes a “higher level of knowledge” – spiritually and intellectually – than the status quo (Yunkaporta 2009). The status quo concerns what exists, which does not have a linear relationship with what will exist. As Fig. 2: *Boomerang Interface of Cultural Interface*

The Parable Proxy of Possibilities,

Fig. 2 Boomerang Interface of Cultural Interface Knowledge

Knowledge demonstrates, a society's understanding increases when it perceives its *different similarities* rather than just its differences. These insights enable learning “*through* culture, not about culture,” with the new perspectives getting “*built in*, not bolted on” (p. 4).

The status quo is an emergent social state that reflects a culture's values. It is a perspective sustained by its myths and metaphors. However, healthy systems are chaotic, requiring resilience and adaptability (Aerts et al. 2012), including responding to change and innovation. When a culture undergoes a transmutation, like in the example of Einstein, its myths and metaphors move in sync, creating an embodied perspective to anchor it in the newly formed status quo. In this light, the PPP is a framework for generating new perspectives to increase potential by enabling an organization to safely *alter* the status quo rather than a creative problem-solving process model that produces novel and useful ideas *versus* the status quo (Runco and Jaeger 2012; Stein 1953). “Prominent ideas cannot die until the problems that arise within them has been resolved” (Samuel and Thompson 2021, p. 15).

That is why the PPP preferences imagination over creativity. It encompasses an expansive array of perspectives, and it is not as constrained by social consensus that can limit possibilities as epitomized by the status quo.

The Importance of Imagination

Since the PPP is powered by imagination, it is worth clarifying this concept as it has received

less research attention than creativity. Runco and Pritzker (2020, p. 637) define it thus:

In the psychological research ‘imagination’ is becoming a broader term that encompasses the multi-faceted capacity to transcend our current time, place and/or circumstances to think about what might have been, plan and anticipate the future, create fictional worlds, become absorbed in the narratives created by others, and consider remote and close alternatives to actual experiences. With this definition, imagination includes everyday mundane thoughts (e.g., plans for dinner), as well as the creative insights that lead to progress in art and science. This definition also distinguishes imagination from imagery, with the latter being a tool of the imagination rather than equated with it.

Imagination is not the same as *imaginary* because “imaginative processes have real world effects on our behaviour” (p. 637). In other words, imagination carries with it the potential for action and actualization while the imaginary is trapped in the abstract. Nor is imagination just the domain of children. Strategizing and remembering are all done using imagination. People pretend when they evaluate options by converting them into narratives that run through their minds. Fantasy, pretending, and storytelling are vital and ageless undertakings that enrich cognitive capacities.

In these “postnormal times” characterized by the 3Cs: complexity, chaos, and contradictions, Sardar (2010, p. 443) argues that society needs imagination more than ever.

The most important ingredients for coping with postnormal times are imagination and creativity. Why? Because we have no other way of dealing with complexity, contradictions and chaos. Imagination is the main tool, indeed I would suggest the only tool, which takes us from simple reasoned

analysis to higher synthesis. While imagination is intangible, it creates and shapes our reality; while a mental tool, it affects our behaviour and expectations. We will have to imagine our way out of the postnormal times. The kind of futures we imagine beyond postnormal times would depend on the quality of our imagination. Given that our imagination is embedded and limited to our own culture, we will have to unleash a broad spectrum of imaginations from the rich diversity of human cultures and multiple ways of imagining alternatives to conventional, orthodox ways of being and doing.

However, Vygotsky's (2004) "first law of the imagination" states that the ability to be creative depends on the "richness and variety" (p. 14) of a person's experiences because that powers their imagination. The richer the person's range of experiences, the more they can indulge in fantasy, embody stretching narratives, and construct complex and layered storylines. The PPP's design reflects this by providing a structured way of creating new storylines to help users continuously shift their perspectives, regardless of the richness of their experiences. Its use of narrative devices helps to question what "they know" to create what does not yet exist. These scenarios can be realistic or fantastical, probable, or even impossible – it does not matter – because it is a matter of perspective. By imagining it, it helps materialize it to close the gap between the possible and impossible.

That is why the PPP is a creative insight generating framework rather than a creative problem-solving process model. By approaching complex challenges this way, the PPP overcomes significant drawbacks of creative problem-solving process models – their narrow perspectives and use of the status quo limiting innovation.

Storytelling

The PPP embodies the wisdom of a multitude of perspectives to continuously generate more possibilities and safely brings them into being with storytelling, which is arguably the most subversive communication medium because it is accepted unquestioningly. "Any writer worth his/her hire knows that all writing, one way or another, is subversive. It is guerrilla warfare

against the status quo" (Ellison 1997, p. 247). Stories provide coherence to events that are recast as a truth that enables an organization to survive and thrive (Lakoff and Johnson 2008). Storytelling is weaved through every cultural medium because it is how society constructs meaning.

The PPP is called a framework, but it is alive and metabolizing its culture's knowledge – the stories that create reality. These narratives give an organization coherence, connection, and kinship. Hence, the PPP has a 3D and hand-drawn element; it emphasizes that it is anchored and embodied.

The inclusion of the word parable in the *Parable Proxy of Possibilities* borrows from the allegorical literature to emphasize that it is a storytelling framework with a moral compass – the spirit of respect. It is not a pre-ordained morality; it is created in the spirit of Confucian philosophy where there is no predetermined truth, so users need to take personal accountability for how they move forward in the world (Li 2006).

The PPP creates narratives using perspectives and storytelling devices like myths and *metaphors* working with the imagination "as a form of enrichment or expansion, of one's experience and understanding of the world" (Zittoun and Cerchia 2013, p. 2). The PPP enriches a culture's potential by embodying a range of perspectives to create relational bridges to the myths and metaphors of the status quo to materialize new possibilities. Therefore, it respects rituals and traditions as well as what is novel and useful (Runco and Jaeger 2012; Stein 1953) because both can engender an "experiential gestalt" (Lakoff and Johnson 2008, p. 234) that creates a coherence through actions to concretize a new reality.

Conclusions

The PPP is created from the conviction that humankind needs to integrate new perspectives to engender a more inclusive and respectful embodiment of this culture's status quo. This culture's current narratives of the future reinforce a win/lose, either/or mentality (Lamp 2020). It contributes to society losing sight that we are

interconnected and dependent. The world is pregnant with possibilities; however, the languaging of today determines what will be available tomorrow. The status quo suffers from a lack of diverse perspectives needed to materialize more opportunities for transformational change. Instead, it appears we are destined for an extension of the present state.

Narratives “contribute to the perspectival nature of reality and open it up to the possible” (Glăveanu 2020, p. 81). Therefore, it is essential that society critically examine how it categorizes knowledge. Instead of characterizing it as different, society could view new perspectives as having *different similarities* or a *similarity of the differences* (Bohm 2004, pp. 60–61). This deliberate languaging allows a culture to play with diversity while respectfully creating discriminations that contribute to knowledge that deepens its understanding.

The PPP is created from the conviction that humankind needs to integrate new perspectives to engender a more inclusive and respectful embodiment of the status quo. It can alter the elaboration of this culture’s current languaging from reinforcing the structures that support and maintain the systems of power (Pettigrew 1979) to languaging that materializes a more enlightened status quo with more inclusive myths and metaphors to engender more possibilities. In this way, the PPP acts as narrative pedagogy that can help shift the relationships between seemingly different groups onto a higher plane.

Acknowledgments I want to thank Wendy Ross, Barbara Doran, and Vlad Glăveanu for many inspiring conversations and insightful feedback on earlier drafts. I would also like to thank Jennifer Gippel for her advice, wise counsel, and determination that helped generate the first iterations of the PPP.

Abstract

This entry presents the positive function of embracing contradictions. It shows that the tension induced by the consideration of simultaneous contradictory ideas may actually be positive, especially in the field of creativity.

In the literature, there appear to be several concepts related or identical to the idea of embracing contradictions: conceptual blending, the paradox mindset, and Janusian thinking. Herein, some examples of contradictions represented by creative individuals are presented. Moreover, it is delineated how the paradox mindset may augment creativity and divergent thinking.

Following this, the entry introduces ways of measuring Janusian thinking and reports the

validation process of a proposed questionnaire. Finally, it concludes with outlining possible future studies and applications in practice.

Keywords

Paradox mindset · Contradictions · Janusian thinking · Conceptual blending · Creativity · Embracing contradictions · Divergent thinking

Introduction

Aristotle gave us, on the one hand, the law on noncontradiction (LNC), which states that opposite assertions cannot be true at the same time; on the other hand, he left numerous paradoxes in his wake, e.g., in a race. In a race, “the quickest runner can never overtake the slowest, since the pursuer must first reach the point whence the pursued started, so that the slower must always hold a lead.”¹ Another example is that if everything that exists has a place, that place too will have a place, and so on ad infinitum. At the meta-level, Aristotle's heritage seems to be a message: The LNC may coexist, in a person's mind, with paradoxes and contradictions.

Following this message, this article explores both approaches: Positing that contradictions generate unpleasant tension that needs to be reduced, and the opposite, arguing that contradictions generate constructive tension to be embraced by individuals.

Cognitive Dissonance: Reducing Negative Tension

The phenomenon of cognitive dissonance (CD) (Festinger 1957; Festinger et al. 2009) is considered to be one of the most influential theories in psychology. It posits that making a new choice that is not consistent with prior beliefs or attitudes kindles CD, which is experienced as unpleasant and is hence reduced through various mechanisms, e.g., rationalization, so that one's prior beliefs are altered so as to be more consistent with their actions.

¹Aristotle, Physics VI:9, 239b15.

Leon Festinger (1957) stated that CD occurs when there is an uncomfortable tension between two or more beliefs or concepts that are held simultaneously. Additionally, most people want to perceive themselves as cohesive, and inconsistencies would contradict their self-image. In this vein, one restructures their internal beliefs in order to reduce such CD and to reach a state of internal cohesiveness on this new level (Mischel 1969, 1973).

Positive Role of Tension Evoked by Contradictions

As written by Johann Wolfgang von Goethe, “What we agree with leaves us inactive, but contradiction makes us productive.” This means that it is the very process of dealing with contradictions that fosters productivity, which energizes and inspires an individual to perform under tension. This is also reflected in Friedrich Nietzsche’s *Twilight of the Idols*: “One is fruitful only at the cost of being rich in contradictions.”

It is not only philosophers and writers who have discovered the importance of contradictions. Similar voices also come from business, e.g., Joel Gascoigne, a startup founder, said that the success of a new venture might be dependent on a willingness to embrace inconsistency and to contradict oneself.² For example, Rothenberg (2011) showed that among the winners of the Nobel Prize, the common process is actively and simultaneously conceiving and holding multiple opposites. Additionally, leaders who embrace a paradox mindset are more likely to enhance the productivity of their workforce (Liu et al. 2019).

Another example is Jeff Bezos, an entrepreneur, investor, and computer scientist best known as the founding CEO of Amazon, who said that people who are usually right frequently change their minds, and that consistency of thought is not at all a particularly positive trait. Indeed, he encourages leaders to challenge

themselves with ideas that contradict their previously held convictions.³

Moreover, Peter Senge (2006) described constructive tension, also called creative tension, as the “gap between vision and current reality,” where possibility and constraint meet, which is vital to create peak-performing organizations.

Indeed, it has been shown many times that tension can create focus, heightened activity, and maximum productivity (McGoff 2017).

An Overview of Embracing Contradictions

A paradox mindset involves individuals accepting, embracing, and being energized by the tension caused by contradictory ideas. The acceptance of a paradox mindset can help people enhance creative drive (Miron-Spektor et al. 2017; Liu et al. 2019). In this sense, a paradox has to be accepted, adjusted to, and made sense of, both in life and at work, as well as in the community and among nations (Handy 1995). Below is an overview of the various approaches to embracing contradictions.

Conceptual Blending

Conceptual blending is a form of novel idea creation based on combining two concepts (Oakley 1998). It is a fundamental instrument of the everyday mind, used in the basic construal of all realities, from the social to the scientific (Turner 1997, p. 93). Elements and vital relations from diverse scenarios are “blended” in a subconscious process (Fauconnier and Turner 2003).

Conceptual blending is a cognitive aptitude enabling performing a variety of functions – from event integration, conceptual change, and metaphor projection to humor, literary invention (Oakley 1998). An example of conceptual blending is the conceptual metaphor theory (CMT), which states that metaphors are a conceptual – rather than a purely linguistic –

³ <https://signalvnoise.com/posts/3289-some-advice-from-jeff-bezos> (accessed 20 March 2021)

phenomenon (Grady et al. 1999; Handl and Schmid 2011).

An important type of conceptual blending is divergent thinking, i.e., connecting concepts, even if they are disparate and unrelated – a kind of creative cognitive processing (Guilford 1950; Runco 2007). Indeed, divergent thinking is an indicator of creative potential (Runco and Acar 2012).

This article focuses on the kind of conceptual blending that relates to merging contradictory concepts, called the paradox mindset or Janusian thinking.

Paradox Mindset

A paradox mindset indicates the extent to which an individual embraces and is energized by tension. For employees, a paradox mindset has a positive impact on their innovativeness. For example, leaders' paradox mindset is positively associated with employees' innovative work behaviors (Liu et al. 2019).

Individuals that possess a paradox mindset (i.e., those who accept and are energized by tension) respond to a contradictory situation by developing a sense of optimism about being able to successfully work through said situation. A paradox mindset is also associated with determination and persistence, even if stuck or failing (Sleesman 2019).

Janusian Thinking

"Janusian thinking" is a process named after Janus, a Roman god who has two faces, each looking in the opposite direction. Janusian thinking involves the ability to imagine two opposites or contradictory ideas, concepts, or images existing simultaneously (Michalko 2012). It may also be seen as a process that allows an individual to think paradoxically. Not many people are able to engage in Janusian thinking, because it requires the ability to see the two sides of a paradox in order to transcend it and to find the optimal "solution"; instead, the majority of people are typically only able to perceive a single side (Mostovitz et al. 2008).

The analysis of the creative work of contemporary, and of those of past years, outstanding

scientists indicates the significant role in scientific invention of Janusian thinking, i.e., actively conceiving multiple opposites or antitheses simultaneously (Rothenberg 1971, 2011). This cognitive process is related to Einstein's description of his discovery of the general theory of relativity: For example, Einstein described one of his thoughts in the development of the general theory of relativity, i.e., finding out that a man falling from the top of a house was both in rest (relatively) and in motion at the same time (Michalko 2012; Rothenberg 2015).

Paradox Mindset and Creativity

The paradox mindset and contradictions can impact previously held assumptions, allowing to perceive a situation from a whole new perspective. This is essential in creativity, often referred to as overcoming an impasse, as creative acts, particularly moments of inspiration or "a-ha" moments, deliver a feeling of joy, which in turn stimulates the brain plasticity essential for creativity (Pellis and Pellis 2009).

Indeed, creative people are well known to embrace contradictions and paradoxes (Miron-Spektor et al. 2011; Miron-Spektor and Erez 2019). For instance, Miron-Spektor et al. (2011) and Miron-Spektor and Erez (2019) demonstrated that those who are better able to hold contradictory ideas are more likely to be "outside the box" thinkers, a trait that is often cited as essential for creative endeavors. Moreover, Miron-Spektor et al. (2011) showed that those who are able to reflect on opposing ideas are more creative than those only capable of considering a single concept.

Generating creative ideas by exploring opposite solutions is also called divergent thinking. Divergent thinking remains the most frequently used indicator of creativity in both creativity research and educational practice (Baer 1993).

An overall analysis of the data regarding the creative work of contemporary and past outstanding scientists indicates the significant role of the Janusian process in scientific creation

(i.e., actively conceiving multiple opposites or antitheses simultaneously). This process is complex, involving four phases that develop over extended periods of time: (1) motivation to create, (2) deviation or separation, (3) simultaneous opposition or antitheses, and (4) construction of the theory, discovery, or experiment (Rothenberg 2011).

Some posit that to be creative, one has to continuously contradict oneself using the following mechanisms:

- Having knowledge but often relying on intuition instead
- Seeing unexpected and unusual connections while remaining sane and not having a mental disorder
- Working hard, but also spending time doing nothing
- Generating many ideas, most of which are useless
- Looking at the same thing as everyone else, yet seeing something different
- Desiring success, but learning how to fail (and learning from failures)
- Being persistent but not stubborn
- Listening to experts, but knowing how to disregard them (von Oech 2008)

Moreover, people who are creative tend to have “antithetical traits,” meaning that they possess traits that are in direct opposition, such as the following:

- They have a great deal of physical energy, but are often quiet and at rest
- They enjoy and practice playfulness, but also operate under strict discipline
- They alternate between imagination and fantasy at one end and a rooted sense of reality at the other
- They merge opposite tendencies on the continuum between extroversion and introversion (which is unusual, as psychologists hold that being either an extrovert or introvert is a stable personality trait)
- They are remarkably humble and proud at the same time

- They have both a rebellious streak and a strong culture of basic (traditional) points of reference
- They are both passionate and objective about their work (Csikszentmihályi 1997)

Influence of Contradictions Questionnaire (ICQ)

In order to investigate how individuals feel about holding conflicting concepts, we created and tested the Influence of Contradictions Questionnaire (ICQ). The source of inspiration for the ICQ was the Paradox Mindset Questionnaire, developed and applied by Prof. Ella Miron-Spektor and her team (Miron-Spektor et al. 2017). However, the applied questions were all positive, which – through the mechanism of social desirability bias (SDB) – may influence respondents. Along these lines, after receiving Prof. Ella Miron-Spektor’s permission, the ICQ was constructed, modifying the original questionnaire and blending positive and reversed statements.

The initial 12 statements were validated in an Anglophonic population ($n = 120$). Of the 12 initial statements, 10 were identified as having good discrimination power ($M = 0.4$; $\text{Max.} = 0.56$; $\text{Min.} = 0.29$; $SD = 0.18$) and good reliability (Cronbach’s $\alpha = 0.779$). Factor analysis did not confirm our original hypothesis that the responses fall into the two categories of “cognition” and “energy” (i.e., action).⁴ The final questionnaire is shown in Table 1.

The validation process demonstrated that the ICQ is appropriate for scientific purposes, e.g., a comparison between segments of society.

Conclusions

Herein, it was shown that being able to hold and deal with conflicting concepts brings about many benefits, such as fostering creativity and

⁴The varimax rotation method was applied, verifying options for two and three components; however, it was decided that one overall component best fitted the data.

Paradox Mindset, Table 1 The influence of contradictions questionnaire

1	I am comfortable dealing with simultaneous conflicting ideas
2	I avoid dealing with conflicting concepts ^a
3	Tension between ideas mentally blocks me ^a
4	Encountering conflicting perspectives makes me confused ^a
5	Tension between ideas energizes me
6	I feel disempowered when dealing with contradictory issues ^a
7	When I consider conflicting perspectives, I gain a better understanding of an issue
8	I feel dejected when I see opposites coexisting ^a
9	I find dealing with conflicting ideas inconvenient ^a
10	I feel energized when I consider addressing contradictory issues

^aReversed

enhancing leadership skills. It paves the way for exploring the possible and – drawing from the coexistence of conflicting ideas – to play with future scenarios (Glăveanu 2018).

For further development of our understanding of Janusian thinking, the ICQ is an invaluable tool. Indeed, the validation process documented that the ICQ can be used for scientific purposes, e.g., a comparison between segments of society or finding possible correlations with other personality traits.

Future Studies

In future studies, the ICQ could be tested in a larger population. Other areas worth further investigation are the correlations with various personality traits, especially with ambiguity tolerance (AT) – the psychological construct that describes the relationship between individuals and ambiguous stimuli or events (Furnham and Marks 2013; Norton 2010). The conjecture is that people with higher AT will be more prone to embracing contradictions. Moreover, Janusian thinking could be a predictor of a higher empathy level, as understanding the perspective of others often requires considering a contradictory perspective to one’s own (Gerace et al. 2017).

It also seems important to verify the level of acceptance of the paradox mindset between various cultures. The first step has already been taken

by comparing the Chinese and Western approaches to contradictions: The Chinese way of dealing with contradictions was observed to be a dialectical or compromise approach by seeking a “middle way,” whereas European-American ways, derived from a lay version of Aristotelian logic, were shown to result in a polarizing model in an effort to determine which fact or position is correct (Peng and Nisbett 1999; Keller et al. 2017). Thus, it would be valuable to see the similarities and/or differences between other cultures as well.

Finally, future studies may verify the hypothesis that social entrepreneurs, while addressing seemingly insurmountable problems and struggling with obstacles, consider and embrace contradictory opinions for understanding the complexity of a challenge (Praszkier 2019).

Application

In the field of peacemaking, possessing a paradox mindset may influence one’s peacemaking (bipartisanship) propensity and aptitude. For example, conflicting parties often need help to become more psychologically ready to enter a peace process (Rifkind and Yawanarajah 2019). In this context, the ICQ may serve for verifying the training results of future peacemaking leaders.

Furthermore, most of the paradoxes analysis was aimed at the organizational level. However, individuals and their social interactions often serve as the microfoundations for higher-level organizational paradoxes. Hence, it seems that a more in-depth consideration of paradoxes needs to focus on the individual and team levels of analyses (Schad et al. 2016; Waldman et al. 2019). Within the realm of business, the acumen for embracing contradictions is highly sought after, especially in coping with obstacles (Andriopoulos 2003; Spreitzer 2020) or “feeling into” a competitor’s position or latent (future) market demands (Heracleous 2020; Heracleous and Robson 2020).

In summation, a paradox mindset is helpful in breeding future leaders, especially when preparing the younger generation for taking on pressing challenges containing ambiguities and contradictions (Tian and Smith 2015; Praszkier 2019).

Participation · Roles · Common purpose · Socio-cultural theory · Social action · Democratic engagement · Power · Justice · Collaboration

Introduction

This entry explores the concept of participation as a means to pursue the possible. Participation can be defined as *uniquely contributing to an activity*

or common purpose along with others. Participation may take place in any number of environments, take many different forms, and involve complex social interactions. When taking a *participatory* approach to a given process or practice, it is suggested that multiple actors will be involved in that process or practice in a manner that is distributed and democratic, and in a manner that further leverages the strengths of each contributing participant. Context is also important to participation. The concept may therefore be described in very local terms – or considered more globally. This entry begins by situating participation within a broader academic landscape before defining the concept of participation in concrete terms. The entry then discusses the core principles of participation, contrasts participation with collaboration, and then closes with a discussion of participation and the possible.

Background

Participation is a general enough term that can be found in any English language dictionary – with more or less similar meanings being expressed across other languages. In a more specific application, wherein participation may be seen as a means to pursue the possible, the concept has several practical and scholarly connections. Four such connections include *participatory culture*, *participatory action research*, *participatory creativity*, and *JusticexDesign*.

Participatory Culture

As digital connectivity has increasingly become more and more a part of life and work, many scholars have been prompted to investigate the social interactions we experience online. Jenkins (2019) and his colleagues (Jenkins et al., 2009, 2015) have applied the term *participatory culture* to young people's engagement with online platforms. From Jenkins and his colleagues' perspective, young people – especially teenagers – participate in many different online cultures. These cultures may include video sharing platforms such as TikTok, YouTube, and Vimeo; knowledge sharing platforms such as Wikipedia,

Urban Dictionary, and various Fandoms; coding platforms such as Scratch; online gaming or sandbox platforms such as Minecraft; or any number of social media platforms such as Facebook, Instagram, Snapchat, or Twitter. By the use of these platforms – and a multitude of others – young people (and adults) may engage with content, upload content, like or comment on content, be influenced by (or influence others with) content, or hack, redesign, and re-upload content. Any time they do so, they are participating in one, if not many, online cultures. Jenkins and his colleagues argue that participating in digital cultures in this way yields a variety of benefits to young people, including learning from one another, acquiring twenty-first-century workplace skills, and engaging in civic discourse. The challenge, however, is to support all young people in having equal access to these online cultures while also providing them with the digital and media literacies necessary to be effective and responsible participants within these participatory cultures.

Participatory Action Research

For decades the concept of *action research* has become popular throughout many fields (see for example Whitehead, 2006 and the *Action Research* journal).¹ Generally speaking, action research involves a significant level of engagement between the researcher and the subject being studied. The outcome of such a study is action, not just generalizable knowledge. In some instances, the researcher is the subject herself, as it is her own practice that is being studied through a structured inquiry process. Taking a *participatory* approach to action research involves a heightened level of exchange between the researcher and the research subject. Both qualitative and quantitative in practice, participatory action research (PAR) often takes a more democratic and social justice-oriented stance toward the process of research. A comprehensive representation of participatory action research can

be found on the Participatory Methods (n.d.) website:

There are many definitions of the approach, which share some common elements. PAR focuses on social change that promotes democracy and challenges inequality; is context-specific, often targeted on the needs of a particular group; is an iterative cycle of research, action and reflection; and often seeks to “liberate” participants to have a greater awareness of their situation in order to take action (para 1).

As expressed by these elements of participatory action research, the practice is distributed, democratic, critical, and inclined toward outcomes that affect positive change – especially for the participants in the study.

Participatory Creativity

Stretching back to the late twentieth century, there has been growing interest in moving beyond individual orientations toward creativity to support more socially distributed approaches to invention and innovation. To this end, many books and journal articles have been written about group creativity (see for example Paulus & Nijstad, 2003, 2018; Sawyer, 2003), collaborative creativity (see for example John-Steiner, 2000; Miell & Littleton, 2004), and distributed creativity (see for example Glăveanu, 2014; Sawyer & DeZutter, 2009). Social approaches to creativity (often called *systems-based* approaches to creativity) have picked up so much momentum that, as recently as 2019, a consortium of over 20 leading creativity researchers published a manifesto supporting a socio-cultural stance toward creativity (Glăveanu et al., 2019). Within the mix of positions on socio-cultural creativity theory is *participatory creativity* (Clapp, 2016; Clapp & Hanchett Hanson, 2019; Clapp & Rains, in press; Hanchett Hanson, 2015; Hanchett Hanson & Clapp, 2020). Participatory creativity is a socio-cultural approach to creativity that emphasizes the participation of multiple actors within the creative process. From a participatory perspective, creativity develops by the unique contributions of many individuals in pursuit of a common goal. Individuals play various roles when they participate in creativity, but those roles are neither fixed nor

¹To learn more about the *Action Research* journal, see <https://journals.sagepub.com/home/arj>

unidimensional, but rather dynamic and flexible (Clapp, 2016). Like participatory action research, participatory creativity emphasizes a democratic stance toward invention and innovation, and often results in a collective sense of cultural empowerment (Glăveanu & Clapp, 2018). Furthermore, access and equity are elemental to participatory creativity. As the theory and related framework asserts, taking a participatory approach to invention and innovation provides all individuals to engage in the creative process, not just those who may be identified as *being* creative by traditional standards.

JusticexDesign

Building on the mounting empowerment trend of participation and the possible, the JusticexDesign framework for learning (Sheya et al., 2020) takes a critical stance toward maker-centered learning (Clapp et al., 2016), a popular pedagogical practice that involves incorporating making into various educational settings. The JusticexDesign framework (Sheya, 2022) argues that beyond the technical skills taught in schools and after school programs, *power*, *representation*, and *participation* are inherently at play within the design and making process. The framework prompts young people (and adults) to be critical consumers of the designs that they encounter – especially the designed-nature of systems of power. Three pedagogical principles shape the JusticexDesign framework: *design is not neutral*, *power is multi-dimensional*, and *participation is constructed* (Solis & Sheya, 2021). Regarding participation, Sheya et al. define the concept as such:

Participation can be understood as the various ways in which people engage with and contribute to the systems they interact with through the process of making. ... JusticexDesign's pedagogical principle *participation is constructed* manifests when students (a) look closely at oneself; (b) become sensitive to the design of participation; and (c) listen and speak bravely. (p. 18)

Interestingly, Sheya et al. argue that participation itself is a socially constructed – and designed – concept. By becoming sensitive to the design of one's participation, one may engage in the act of

critical participation. Individuals “come to see [the] complex ways their identities shape their interactions with, and reactions to design. . . and construct a new or different design that better reflects their ideas, values, and perspectives” (p. 19). By looking closely at oneself and developing a sensitivity to participation, one can then listen and speak (and act) differently. In other words, by looking critically at the socially constructed nature of one's own participation in a variety of designed systems (especially systems of power and oppression) one may change the way she participates within those systems to pursue the liberation of self and other – and the greater goal of justice.

Participatory culture, participatory action research, participatory creativity, and JusticexDesign represent just a few examples of the many ways in which participation has been employed to support the possible. While each has their own specific take on participation, some common themes include social interactions with others, the pursuit of positive outcomes, the democratization of engagement, and an inclination toward justice. Beyond these examples, when talking generally about the relationship between participation and the possible, it is helpful to have a foundational definition as a point of reference.

Defining Participation

Participation may take place in any number of environments, take many different forms, and involve complex social interactions. When taking a *participatory* approach to a given process or practice, it is suggested that multiple actors will be involved in that process or practice in a manner that is distributed and democratic, and in a manner that further leverages the strengths of each contributing participant. Context is also important to participation. The concept may therefore be described in very local terms – or considered more globally.

To keep things simple, participation is herein defined as *uniquely contributing to an activity or common purpose along with others* (Clapp & Rains, *in press*). Though simple to understand on

the surface, this definition without frills actually has four parts that are worth further discussion: *uniquely, contributing, activity or common purpose, and along with others.*

Uniquely

When individuals participate in an activity or common purpose of some kind, they do so in unique or specific ways. Here, the term *role* that is prevalent throughout participatory creativity is key. Individuals play unique roles when they participate in an activity or common purpose. The uniqueness of one's participation may be expressed in several ways. First, by the very role that an individual plays – or *uniqueness of role*. While the role one plays in a participatory activity or common purpose may not be uniquely specific to oneself, it may be distinct from the roles that others play in pursuit of a shared activity or common purpose. Think for example, of the role an outfielder plays on a baseball team. Whereas there is only one pitcher, catcher, first baseman, second baseman, shortstop, and third baseman on the field at a time – there are three outfielders. The collective role the outfielders play is different in function and responsibility from the role that the infielders play – even if the outfield position is similar across the three players. Second, the way one expresses her role, or *role expression*, may be unique. We can think back to our outfielders on the baseball team again. Yes, the general function and responsibility of an outfielder may be similar from one of the three players to the next, but there is also differentiation in the role, as there is a right fielder, a center fielder, and a left fielder – and each of those positions have different functions and responsibilities. But the way each of those outfielders plays their position is bound to be different – or unique – from one player to the next as well. In fact, a player in any position on a baseball team might express their role in that position differently from a player in that same position on another team. Third, there is the *personal uniqueness of self* that an individual participant brings to the greater collective. Here, personal uniqueness of self may be understood as the distinct social and cultural perspectives one carries with them,

along with their unique skills, talents, and background experiences.

Contributing

The creativity theorist Howard Gruber once described the creative process as *purposeful work* (Gruber, 1988). The point Gruber was making with this powerful phrase was twofold. First, that creativity is intentional, and second, that creativity does not just come as a flash of insight out of nowhere – it requires effort over time. The same can be said of participation: it requires intention and effort over time.

In order to participate in an activity or common purpose along with others, one has to do the work that the activity or common purpose demands. Doing the work of participation can be described as *contributing* to an activity or common purpose. As discussed above, there is not one way, but rather multiple ways to uniquely contribute to an activity or common purpose.

One may actively contribute to an activity or common purpose by doing the work in the moment that the work is taking place. This form of *actively contributing to participation* involves consciously enacting one's efforts to meet the goals of the activity or common purpose. If we refer back to our baseball metaphor, the players on the field during a game are actively participating in the game – or actively contributing.

One may also *passively contribute to participation*. How might this be? While passively contributing to an activity or common purpose may take different forms, one such example is when an individual may have done the work of participation in the past, while her efforts are playing a role in the present. The originators of the sport of baseball may not be actively contributing to the opening game of the 2022 Little League World Series, but the past roles that those individuals have played, and the efforts they have exerted, still have an effect on that game. Different from actively contributing to an activity or common purpose, passively contributing to participation may not involve a conscious awareness or intention of the role one's efforts may play in a future or parallel endeavor.

Activity or Common Purpose

The phrase *activity or common purpose* has been used a lot in the paragraphs above. An activity or common purpose may be understood as a collective endeavor or initiative that is pursued by a broader group of individuals. Some activities and common purposes are very specific and localized – like participating in a baseball game. Other activities and common purposes may be much broader – like participating in a capitalist economy, participating in democracy, or participating in a social change movement like the #MeToo or Black Lives Matter movements. The word *activity* is used here to suggest that the collective endeavor involves action. Whereas the phrase *common purpose* is used to suggest a shared intentionality and outcome.

Along with Others

The last part of the definition for participation presented herein is *along with others*. This is perhaps the most straightforward aspect of the definition – with an added twist. The phrase *along with others* suggests that participation does not happen in isolation, participation always involves the unique contributions of various individuals. Is it possible for one to engage in purposeful work on one's own? Perhaps (though however unlikely), but that individual's purposeful work would not be considered participation as it lacks the coming together of one's own unique contributions with the contributions of others. Seemingly working alone, it is still possible that one may be participating in an activity or common purpose along with others. Similarly, working at a geographic distance from others, one may still be participating with others. In this way, the concept of *along with others* is expansive, and may allow for the asynchronous and geographical distribution of uniquely contributing participants.

Combined together the four elements discussed above comprise the simple yet multi-layered and variable definition for participation stated at the top of this section: *participation can be defined as uniquely contributing to an activity or common purpose along with others*.

Core Principles of Participation

In addition to the various aspects of the definition for participation that have been parsed out above, there are also several core principles for participation that will be briefly described below.

- *Participation is inherently distributed:* Participation does not occur in isolation, but rather takes place among and across a broad swath of individuals. These individuals may actively or passively contribute to a shared endeavor and may or may not be geographically proximate to one another. Even when one appears to be working alone, one may still be consciously or unconsciously/intentionally or unintentionally participating in a collective activity or common purpose with temporally or geographically distributed others.
- *Participation may be anti-individualism, but it is not anti-individual:* Given the distributed nature of participation, it is a practice that favors the collective over the pursuits of lone individuals. In this sense, participation can be seen as a stance toward the possible that is counter to models of individualism that root feats of achievement in the efforts of sole individuals (who are often described as *gifted* or *exceptional* against some narrowly focused traditional standard for achievement that inclines itself toward the values and interests of a dominant culture). Here, it is important to draw a distinction between *individualism* and *individuals*. Participation is not an anti-individual approach to the pursuit of the possible. Quite the contrary. Participation places high value on the unique contributions of various individuals within a larger ensemble of actors. It is fair to say that participation is not possible without the individual uniqueness that diverse participants bring to collective work. It is also fair to say that participation may place an even higher premium on individual uniqueness within a collective than other socially distributed approaches to the possible.
- *Participation places an emphasis on different roles being played by each participant:* By uniquely engaging in participation, each

participant plays a specific role as they engage in a collective activity or common purpose. Even when the roles being played by one or more participants within a collective may be similar, the expression of role and what each person uniquely brings to that role may be highly variable. It is important to note, that the roles individuals play in the pursuit of activities or common purposes are neither fixed nor unidimensional, but rather flexible and dynamic (Clapp, 2016).

- *Participation is inclusive and democratic:* With its distributed nature and its emphasis placed on roles, participation is inherently inclusive and democratic. Taking a participatory approach to an activity or common purpose invites (if not demands) diversity of many sorts, while also providing a role for everyone to play within a collective endeavor. There is no one way to engage in a participatory activity or common purpose, but rather multiple ways to uniquely contribute to such objectives.
- *Participation is justice leaning:* The inclusive and democratic nature of participation inclines itself toward outcomes that are justice leaning – if not explicitly geared toward justice agendas. Participation’s justice leaning inclination further prompts pursuits of the possible that are oriented toward issues of inclusion, diversity, equity, access, and belonging in either process or purpose.
- *Participation is not equal to collaboration:* As will be discussed in the following section, participation is not equal to collaboration. Whereas participation places an emphasis on roles and the unique contributions of various individuals, collaboration is colloquially understood as *everybody doing everything together*. This is a nuanced, yet significant, difference between participation and collaboration as related approaches to the possible.

Contrasting Participation with Collaboration

Like participation, *collaboration* is a valuable socially distributed approach to the possible.

And while there may be many similarities between collaboration and participation, there are also stark differences.

Broken down to its root word and prefix, the word “collaborate” can be restated as “co-labor.” Co-labor can be literally understood as *everyone doing everything together* within a socially distributed endeavor. Working along with others toward a common purpose are surely key tenets that are shared by both participation and collaboration, but it is within the nuance of how the work is done that the two approaches to the possible diverge.

While participation explicitly places an emphasis on different roles being played by unique contributors, the most commonplace understanding of collaboration is limited to what co-laboring suggests: *everyone doing everything together*. But *everyone doing everything together* implies the duplication of narrowly focused work efforts in a manner that is less inclusive, democratic, or effective as providing the opportunity for a variety of unique individuals to bring the best of their diverse selves to an activity or common purpose as they each play a breadth of dynamic roles.

In a book chapter entitled “Don’t Call it Collaboration!: Reframing Success in Teams from the Perspective of Participatory Creativity,” Clapp (2020) makes a distinction between collaboration and participation, claiming that participation is a more inclusive, efficient, and successful approach to work in teams. Clapp uses the example of a soccer team to make this point: to the naïve observer, a soccer match may seem like everyone on the field running after the ball at once, but more astute observers of the sport understand that each player on the field has a specific role to play. During a soccer match, each player *participates* by playing her role on the team – however dynamic that role may be.

Clapp further makes a distinction between a colloquial *everyone doing everything together* understanding of collaboration versus the more nuanced, role-oriented, and individual uniqueness approach to social engagement that participation presents. Writing on the topic of “creative work in teams,” he notes:

Whereas a colloquial understanding of teamwork as collaboration . . . duplicates efforts, limits the ways that individuals may participate in creative work, and misses out on the opportunity to explicitly invite the diverse talents, skills, background experiences, and cultural perspectives that unique individuals bring to creative work . . . A participatory approach . . . distributes creative work among[st] a variety of individuals, each of whom plays unique roles that are dynamic and multidimensional, promotes the development of unique profiles of participation, and actively invites the diverse talents, skills, background experiences, and cultural perspectives that unique individuals bring to creative work. (106)

Of course, the scholarship on collaboration is vast (see for example Plucker et al., 2015), and many academic definitions of collaboration stretch beyond a simple *everyone doing everything together* conception of the term. Some theorists have foregrounded the role that identity plays in collaborative endeavors (see for example Moran & John-Steiner, 2004) while others, such as John-Steiner (2000) have “categorised [sic] collaboration based on roles, working methods, and levels of commitment” (Moran & John-Steiner, 2004, p. 13). Indeed, many other theorists have put forth nuanced orientations toward collaboration that align with the concept of participation as it has been presented. Nevertheless, the reductionist *everyone doing everything together* understanding of collaboration persists.

It is very likely that, in practice, many forms of what is casually referred to as collaboration are actually more participatory experiences than they are redundant co-laboring experiences. Nonetheless, if the goals of a socially distributed approach to the possible are meant to reach toward the core principles of participation as stated above, then it is advisable to make the implicit shift away from a co-laboring approach to practice – to one that is more participatory by design.

Participation and the Possible

Simply defined as *uniquely contributing to an activity or common purpose along with others*, participation is a multi-layered and socially distributed approach for pursuing collective

activities or common objectives. It is also a concept that is rich with potential for the possible.

As our world becomes more interconnected, the work of individuals acting in isolation – without any connection to the collective work of others – is likely to become less and less a part of our personal, professional, and creative lives. Even as the Internet and other telecommunication advances have made it possible to “work remotely,” the very nature of work – and of life – is inherently more about the coming together (virtually or IRL) of diverse people, with diverse talents, skills, experiences, and perspectives, each playing a wide variety of roles to achieve mutual meaningful goals. Participation not only provides us with a foundation by which to base such socially distributed work, it also foregrounds – if not necessitates – diversity in various forms. Pursuits of the possible may not only become more productive by the enactment of participation, but they may also become more rich, relevant, and meaningful as the unique contributions of unique individuals bring to bear the power of diversity through the participatory process.

The pursuit of the possible may be further bolstered by the key points of inclusion, diversity, equity, access, and belonging – and the democratic and justice leaning nature of participation. As this entry is being written during the third decade of the twenty-first century, the world is struggling with these very issues. From South Africa to South Carolina, inequities that have long existed along the lines of race and class have become all the more apparent due to the global pandemic known as COVID 19. The increased awareness – and frustrations – associated with these inequities have resulted in campaigns to support greater inclusion, diversity, equity, access, and belonging agendas throughout almost every social sector. At the same time, the very foundations of democracy are being threatened across the globe, as nationalism, political polarization, hate speech, xenophobia, and racial violence and injustice are on the rise. All this before even mentioning the escalating crises of climate change and environmental degradation that the world faces each day.

There is perhaps no time more ripe than now for participation to shape not only the possible – but what’s best for our global well-being and our world future. Here, it is helpful to refer back to the JusticexDesign principle (and provocation) that puts forth the idea that participation is socially constructed by both the self and others (Sheya et al., 2020). If we are to look closely at ourselves, and look critically at the ways that we participate in the designed dimensions of our worlds – then we may be able to engage with others to enact our collective agency by purposefully participating otherwise to affect positive change.

Considering the wicked problems we face today on so many institutional and structural levels, now more than ever, our hope for what *is possible* requires participation – both locally and globally – from as many unique contributors to the common good *as possible*.

At the end of the day, participation is power. The potential for each person to engage in participation is directly related to the potential each person has to shape their worlds.

Peace-Oriented Mindset

Ryszard Praszkiar¹ and Paige Munnik²

¹Institute for Social Studies, Emeritus, University of Warsaw, Warszawa, Poland

²School of Psychology, University of Buckingham, Buckingham, UK

Abstract

This entry focuses on intractable conflicts, which have multiple and a complex components. It reviews various peace-maintaining actions, especially those focusing on building an environment that contributes to damping down conflicts and to preventing their outbreak.

The role of the peace-fostering environment is presented both from the perspective of the dynamical system theory, as well as illustrated by case studies, leading to a review of peacebuilders' specific personality characteristics. Moreover, multifactorial delineation of the aptitude for fostering peace, especially if intractable or looming, is presented.

This delineation led to the process of constructing the peace-oriented mindset (POM) questionnaire, as presented in this entry.

The conclusions are that a better cognition of peacebuilders' characteristics may contribute to identifying and training the best leaders in the field of peace maintaining and prevention.

Keywords

Conflict resolution · Conflict prevention · Peacebuilding · Peace psychology · Alternative attractors

Introduction

Conflicts may be active or dormant, violent or obtuse, manageable or intractable. In particular, the latter are a tall order for the people, families, groups, and nations involved. On the local level, they usually involve ethnic, religious, cultural, and economic disagreements or clashes – becoming far more complex on the national level. This complexity requires a multifactorial approach to peacebuilding. This entry draws from the existing delineations of maintaining peace, namely, the dynamical peace and conflict theory, and from case studies.

Intractable conflicts endure despite repeated attempts to resolve them. Such conflicts can exist at the family, community, organization, or international level, often becoming difficult challenges (Bar-Tal 2015; Coleman 2003, 2006; Kriesberg 1993). Moreover, they are often perceived as “impossible.” This entry demonstrates an approach that enables turning “impossible” conflicts into “possible” ones, especially when peacebuilders with specific traits are involved.

Maintaining Peace

It is trivial to say that peace is one of the most desirable states. The desire for maintaining peace is often categorized into four dimensions:

- *Conflict prevention*: Action to prevent disputes from arising between the parties involved, to prevent existing disputes from escalating into conflicts, and to limit the spread of the latter when they occur.
- *Peacemaking*: Action to bring hostile parties to agreement.
- *Peacebuilding*: Action to identify and support structures that tend to strengthen and solidify peace in order to avoid a relapse into conflict.
- *Peacekeeping*: Deployment of a United Nations military and civilian presence in the field to expand the possibilities for prevention of the conflict (Reychler 2017; Reychler and Langer 2020).

Documents of the United Nations assign the latter dimension, peacekeeping, into two separate lines of action:

- *Peace enforcement*: The application of a range of coercive measures, including the use of military force.
- *Peacekeeping*: Facilitating political processes; protecting civilians; assisting in the disarmament, demobilization, and reintegration of former combatants; supporting the organization of elections; protecting and promoting human rights; and assisting in restoring the rule of law.¹

For the purpose of this entry, the Peacebuilding and Conflict Prevention categories will be used.

Peace Psychology of the Key Players Involved

Peacebuilding (as defined above) in the area of intractable conflicts requires a specific psychology, namely, developing trust and cooperation (i.e., social capital; see: Coleman 2000; Fukuyama 1996; Putnam 1993); indeed, some people have the propensity for building social capital (Zabłocka et al. 2016). Similarly, conflict prevention requires specific sensitivity for detecting lurking conflicts and empathy in order to preclude their outbreak.

Rifkind and Yawanarajah (2019) indicated that often, the conflict-related psychological atmosphere is one of mistrust and suspicion: “This state of mind keeps conflict parties rigidly and emotionally attached to their positions and often psychologically blocked from being able to engage productively in a peace process and achieve outcomes that meet their best interests. (...) To make conflict resolution efforts more effective, conflict parties need help to become psychologically ready to enter a peace process” (p. 1).

For building such a psychosocial environment, an interactive problem-solving approach is recommended, being a process that changes parties’ perceptions about one another in a way that reconciles them and transforms their relationships – as opposed to focusing on the history of

conflict escalation, which may lead to reversing the dynamics (Kelman 1990).

More specifically, for a constructive peace process, the parties involved should have effective communication; demonstrate friendliness, helpfulness, respect, and fairness; coordinate their efforts; understand the ideas of others; agree to influence others with persuasion instead of pressure; and define conflict as a mutual problem (Deutsch 2012).

This indicates that a specific peace-fostering environment is required.

The Role of the Environment

Maintaining peace, if seen as a lasting and stable process, cannot be solely imposed from outside (e.g., through peace enforcement and peacekeeping); to be durable (e.g., through conflict prevention or peacebuilding), it requires a specific psychological context, one that fosters and maintains peace processes (Halperin 2016; MacNair 2012).

Intractable conflicts in societies lead to developing a specific psychosocial infrastructure, which includes collective memory, an ethos of conflict, and collective emotional orientations. This “around-the-conflict environment” becomes, over time, a key factor reinforcing, in a feedback loop, the core conflict (Bar-Tal 2007).

From this perspective, the essential challenge is to transform the sociopsychological context so that it becomes a peace-enforcing environment (Lederach 2003); this means transforming the environment while reaching beyond the sole conflict itself (Miall 2004).

For example, Dr. Yehudah Paz, from the high-level conflicted Negev area in Israel, posited that people become used to living in a conflict environment; they stabilize mentally, as well as economically, around the conflict.

When peace is suddenly “given” from outside, people feel lost and disempowered in the new, unknown, non-conflict environment, and they may tend to revert to the well-known conflict situation. This indicates restraining from direct conflict resolution attempts prior to transformation of the environment, so that said environment

¹United Nations’ Peacekeeping Terminology, see: <https://peacekeeping.un.org/en/terminology>. Retrieved 2 Dec 2021.

can support and sustain peace, instead of tending to relapse.²

This approach supports the notion of “conflict transformation” rather than “conflict resolution,” including the social, economic, and cultural context (Lederach 1996, 2003). Instead of approaching the peace process head-on and confronting the core conflicting issues, the solution would be to circumvent the conflict and build up a new, supportive environment (Praszkier et al. 2010).

Moreover, this approach enables perceiving and approaching the conflict dynamics as an opportunity for creating constructive change and development (Lederach 2003).

The so-called “Deutsch Crude Law of Social Relations” states that the characteristic processes and effects elicited by a given type of social relationship also tend to elicit this type of social relationship. The cause becomes the effect and vice versa. For example, cooperation *induces* and *is induced* by perceiving similarity in beliefs and attitudes (Deutsch 1973).

This has been confirmed by computer simulations of the possible conditions influencing the rise or decline of conflicts: It seems that conflicts grow exponentially in places with the highest incompatibility of interests, whereas even seemingly intractable conflicts can be transformed by creating a fast-growing, positive process outside of areas inhabited by direct conflict (Nowak et al. 2010).

Given the above, an important question arises: What sort of personality traits enable facilitating conflict transformation (especially if intractable) into a constructive outcome?

Attitudes Toward Peace

One of the earliest attempts to evaluate the psychology of peace-oriented people was a questionnaire built in the 1980s, called Irenometer;³ the result was a ten-statement scale (Bardis 1984).

The reliability has been shown to be good enough, though some doubts have arisen: What about the discrimination power of these statements? It seems that all of them prompt the same answer, e.g., everybody says “Definitely yes” to “Human society does not need an occasional war,” “Peace leads to much greater progress than war does,” or “Historians should never glorify war.”

The second doubt relates to all-positive wording, with no reverse statements, which may influence respondents through the mechanism of social desirability bias (SDB).

More complex research was conducted by an Italian team, who constructed and validated the Peace Attitude Scale (PAS) (Broccoli et al. 2021). A total of 499 subjects were tested with the 42-item form (graded on a 7-point Likert scale). The validation procedures indicated reducing the number of statements to 22, with good reliability. Factor analysis showed that five domains appeared to be relevant (Broccoli et al. *idem*):

- Sociopolitical
- Personal well-being
- Ease with diversity
- Environmental attitude
- Caring

The correlations between PAS and the Big Five were analyzed on a large sample ($n = 121$). Hierarchical regression analysis revealed that two Big Five personality traits, namely, Conscientiousness and Openness to Experience, correlated with peace attitudes (Cavarra et al. 2020). This indicates, among all, that individuals who are more motivated to seek out new experiences also tend to show stronger peace attitudes.

Peace-Oriented Mindset

Maintaining peace, as mentioned in the section “Introduction,” requires a multifaceted approach. In particular, peacebuilding means taking action, i.e., supporting structures that strengthen and solidify peace. Similarly, conflict prevention requires early detection of dormant or latent

²From an interview with Dr. Yehudah Paz led by Ryszard Praszkier, 29 Aug 2009.

³Department of Sociology, University of Toledo, USA.

conflicts, as well as preventing them from relapsing into open conflicts.

In this vein, there seems to be a need for a more dynamic and multifactorial delineation of the properties of a peacemaker, as someone who has sensitivity to lurking conflicts and is determined to take appropriate actions to prevent their outbreak. This property, defined below as a peace-oriented mindset (POM), is universal; individuals differ on the “very high”–“very low” POM continuum scale. Therefore, this entry focuses on individuals with a high POM level.

Computer simulations have confirmed that seemingly intractable conflicts can be transformed by creating a fast-growing, positive process outside of direct conflicting areas (Nowak et al. 2010). In lieu of this, peacemakers should have the capabilities to identify and initiate cooperation “outside of the conflicting area.” In the dynamical approach, these are called “alternative attractors,” i.e., a set of factors solidifying the dynamics around a given equilibrium (Nowak and Vallacher 1998; Säterberg and McCann 2021; Vallacher and Nowak 2007; Vallacher et al. 2010), as illustrated in the following case studies.

Example 1. Addressing Intractable Conflict in the Middle East

Dr. Yehudah Paz’s core conviction was that mere conflict resolution is not enough, as peace leaves a void that is very often difficult for people used to war to bear, especially if they see no other prospects.⁴ Based on this philosophy, he involved partners drawn from clashing groups in profitable joint ventures; through cooperating in these ventures, Jews and Arabs are able to experience the great benefits that ensue from joining forces. These joint ventures result in peace, opening new prospects based on trust and success. Not only do new enterprises appear, but a secondary effect ensues – the empowerment of women, who find themselves at the forefront of building a new economic development of their families and communities. The joint Israeli–Arab approach is reflected in the structure

of Dr. Paz’s organization, which is jointly led by two groups of women: Arab and Israeli.

Families benefit from the new economic ambience and become advocates for peace, as only peace guarantees further development. In light of this, by building bubbles of trust and cooperation, Dr. Paz’s approach also prevents the potential outbreak of dormant conflicts between these two communities (Praszkier and Nowak 2012b).

Following the dynamical peace and conflict theory (Vallacher et al. 2010, 2012), the attractor involved may be illustrated by the metaphor of a ball falling into a hole (see Fig. 1). An outer force (e.g., governmental projects or conflict resolution attempts) is needed to sustain the ball in the upper position (i.e., to mitigate conflict); when the force is removed, natural homeostatic mechanisms cause a setback to the initial state of equilibrium. In a natural way, after an adequately long time, regardless of the action taken, the system has a natural tendency to return to the initial state (equilibrium).

Dr. Yehudah Paz’s approach, instead of focusing on conflicting issues (pushing the ball up), is aimed at building a new attractor (see Fig. 2).

The new attractor, i.e., cooperation, trust, new friendships, and networks, all contribute to building social capital – the environment-transforming factor (Lin 2001; Portes 1998; Woolcock and Narayan 2000). Social capital sustains peace, as in peace ambience, through which multiple benefits are achievable (Praszkier and Nowak 2012b).

Example 2. Conflict Prevention in a Multicultural Border Area

On the Polish–Lithuanian–Belarus border loom deeply ingrained cross-ethnic, cross-religious, and cross-cultural conflicts, which accelerate conflict in a feedback loop, thus impeding economic development and fueling poverty. As demonstrated by Krzysztof Czyżewski, a social entrepreneur from Poland,⁵ implementing various small, community-based initiatives is more effective in

⁴ See: <http://www.nisped.org.il/>

⁵ See: <https://www.ashoka.org/en-us/fellow/krzysztof-czyzewski>. Retrieved 4 Nov 2021.

Peace-Oriented Mindset, Fig. 1 A negative attractor causes the system to relapse, regardless of the actions taken

Peace-Oriented Mindset, Fig. 2 The positive attractor deepens over time, whereas the destructive attractor, which is circumvented and not addressed, automatically decreases

terms of attempting to overcome these conflicts, rather than tackling them head-on. If successful, these initiatives collectively form a new, positive attractor.

In order to restore the region's historical roots, Krzysztof Czyżewski focused on engaging children to publish a local chronicle. In this way, their efforts to collect and exhibit old postcards and photos and trace the multiethnic history of the region were publicized throughout the community, thereby rescuing the historic Catholic, Jewish, Orthodox, and Protestant roots of the area from obscurity.

Teaching traditional crafts and cross-cultural music lessons are some of the other initiatives implemented by Krzysztof Czyżewski, which allow young people to discuss the history and meaning of various traditions. Moreover, such

initiatives allow those local youths who were previously troublemakers and engaged in conflict with mainstream society to revive indigenous Jewish folk music, as well as to play in a national- and international-performing Klezmer orchestra.

As a result of his efforts, Krzysztof Czyżewski has successfully instigated hope and a new vision for the future in the region. The results of the many small initiatives he implemented have accumulated, thereby fostering a shift in the collective mindset of the community and engendering both social and economic development,⁶ subsequently preventing the potential outbreak of underlying

⁶Krzysztof disseminated his approach to many other European conflict regions.

cross-ethnic conflicts in a feedback loop (Praszkier and Nowak 2012b).

Comments on Examples 1 and 2

Dr. Yehudah Paz and Krzysztof Czyżewski are both spearheading peacebuilding. However, there are also people on the ground who are involved in both initiatives and thus often become second-generation leaders. For example, the cross-border project breeds several youth leaders, such as the non-Jewish klezmer ensemble, disseminating Jewish culture to the region and abroad.

This documents that the kind of attitude and acumens associated with building peace are available for all – for leaders, as well as for followers. In this vein, it is essential to be able to identify potential peacebuilding leaders, so as to train and involve them in preserving peace.

Constructing the Peace-Oriented Mindset (POM) Questionnaire

These examples (and many others, see: Praszkier et al. 2010; Praszkier and Nowak 2012a, b) show that there must be a specific peacebuilding-driven mindset. This sort of mindset requires both *cognitive* and *action-oriented* attributes, and, as such, seems foundational for building peace.

Along these lines, the *cognitive* characteristics should encompass awareness of all possible peace options, as well as tolerance of the diversity of beliefs, whereas the *action-oriented attributes* should lead to taking actions aimed at restoring and/or preventing peace. Reflection and operation would hence mutually reinforce one another.

To address the aforementioned objectives of peacebuilding and prevention, the cognitive capabilities include:

- Sensitivity toward possible scenarios and creativity in identifying alternative attractors
- Comprehension of the diverse points of view of the key players involved
- Tolerance of ambiguity and self-confident

As for taking action, peacemakers should be:

- Determined to find ways for crossing the divide

- Anticipatory and inclined to take preemptive (preventive) actions
- Willing to cooperate in the field of peacemaking

These guidelines served as the rationale for constructing subcategories and assigning items to them, as shown in Tables 1 and 2.

To build the POM questionnaire, particular items were assigned to subcategories, as shown in Table 2.

Validation

The initial 18 statements were validated on an $N_1 = 1074$ representative sample of the Polish population. Finally, the 14 statements (out of the initial 18; Table 2) were identified as having good discrimination power (all 14 statements over 0.78) and good reliability (Cronbach's alpha = 0.81).

The factor analysis revealed⁷ that these 14 statements fall into three components, which were labeled as “Cognitive,” “Performative,” and “Doability conviction.”

Discussion and Conclusions

Peace-maintaining processes, especially those addressing “impossible” conflicts and turning them into “possible” peace situations, were analyzed through the lenses of the existing definitions of peacebuilding and preventing, the dynamical peace and conflict theory, and case studies. To see seemingly intractable conflict situations as solvable, one needs a specific personality property called *possibility*, allowing to perceive challenges as doable (Praszkier 2021).

The importance of peace psychology and “conflict transformation” theory (as opposed to conflict resolution) was presented herein, focusing on transforming the sociopsychological context so that it becomes a peace-enforcing environment.

Building this sort of environment in areas of protracted conflicts requires finding alternative

⁷Rotation Method: Varimax with Kaiser Normalization; KMO = 0.884.

Peace-Oriented Mindset, Table 1 POM categories and subcategories

	Categories		Guidelines/rationale	Subcategories
1	Cognition	Awareness of the possible peace options, as well as tolerance to the diversity of beliefs	Sensitivity toward possible scenarios and creativity in identifying alternative attractors	Seeing opportunities for peace, even in the most protracted, intractable, and seemingly insurmountable conflict situations
2			Comprehension of the diverse points of view of the key players involved	Driven to understand the points of view of others, even if they are in opposition to one's own beliefs
3			Tolerance of ambiguity and self-confident	Cognizant that considering other points of view does not equate to shattering one's own convictions
4	Performative	Taking actions aimed at restoring and/or preventing peace	Determined to find ways for crossing the divide	Determined to build bridges between conflicted groups or individuals
5			Anticipatory and inclined to take pre-emptive (preventive) actions	Driven to conflict prevention in situations where conflict is looming/lurking
6			Willing to cooperate in the field of peacemaking	Joining peacemaking groups or organizations
7	Doability conviction	Perceiving challenges as doable	Seeing obstacles as feasible	Perceiving conflict situations as possible to prevent or to reverse back to peace

Peace-Oriented Mindset, Table 2 Items assigned to the subcategories

	Categories		Items
1	Cognitive	Finding neutral common ground	Opposing groups should find some neutral fields of cooperation
2		Listening to others while maintaining own values	Debating with others helps me see the world from a different perspective
3			Listening to others' viewpoints without losing sight of one's own convictions is important for creating peace
4			I can maintain my own convictions, even when they differ to the majority
5		Teamwork	I think that the power of peacemaking lies within teamwork
6			It is best to join a peacemaking organization instead of acting singlehandedly
7	Performative	Preventing conflict	I try to keep peaceful any situation in which conflict could arise
8			I can design an appropriate reconciliation process for a conflict situation
9			Indications that a conflict is looming make me think of how to prevent its outbreak
10		Building trust	I often think about how to foster trust between conflicted groups
11			I can think of innovative ways to build trust between individual parties of a conflict
12	Doability conviction	The ability to contain conflicts	It's possible for me to find an appropriate solution to a conflict situation
13			I feel capable when I see groups in conflict
14		A sense of being able to anticipate conflicts	I think that one can predict a conflict before it breaks out

attractors that foster cooperation, trust, and economic growth. Along these lines, the concept of a peace-oriented mindset was presented, followed by constructing a multidimensional evaluation tool that addresses both cognitive and action-oriented properties.

The presented POM scale, after validation, may serve as a tool for identifying peace-oriented individuals, as well as for training future leaders in this field. Moreover, the POM concept may also be applicable to working and family environments, as conflicts are an unavoidable part of the dynamics of human relations.

Further studies may identify correlations between the POM scale and other personality traits; for example, we hold that it may correlate positively with empathy (e.g., Wakabayashi et al. 2006), ambiguity tolerance (Herman et al. 2010), and paradox mindset (Praszkier and Munnik 2021).

³Mary Lou Fulton Teachers College, Arizona State University, Tempe, AZ, USA

Keywords

Pedagogies of the possible · Difference · Creative experience · Education

Pedagogies are directly linked to the possible, because they aim to open new and varied trajectories for learning and life. Still, many of the pedagogies enacted in formal schooling are restricted by a focus on what is already known and an emphasis on sameness. Pedagogies of sameness constrain the possible particularly when it comes to creative learning experiences (Beghetto and Vasquez *in press*; Beghetto and Yoon 2021). Paulo Freire has arguably (see Chapter 4, Matusov 2009) offered the most famous critique of pedagogies of sameness in his 1968 landmark book, *Pedagogy of the Oppressed* (Freire 2014), in which he made a strong argument against the “banking model of education.” This is a model based on the teacher making mental deposits within the student. A unidirectional transfer of knowledge and information in which teachers know best and know more, and students, as passive recipients, are guided to know what the teacher already knows. Working in the context of twentieth century

Brazil, Freire was sensitive to how this type of education not only limits the agency of students, but potentially contributes to colonizing their minds and to the oppression of marginalized groups within society. If one learns about how disempowering it can be to be part of a specific community, this belief ends up being internalized and curtails further action. Freire's aim was to help individuals and communities go through a process of "conscientization" in which educational banking deposits are questioned and people develop, through dialogue, a realization of their oppression and start reclaiming their agency, creativity, and future.

There is much to learn from this pedagogical principle, including in contemporary classrooms. In a day and age in which we struggle to respond to the racism, sexism, and xenophobia embedded deep within society, educators around the world have the responsibility to advance equity and social justice and the first step in this long process can be guided by Freire's conscientization. Twenty-first century education reckons with these and a broad matrix of problems, including the climate emergency and the realities of a (post) pandemic world. These combined challenges call for a new, radical rethinking of pedagogy, one that recognizes oppression as well as possibility. An education that continues its transformation from passing on knowledge and skills, as part of the banking model, to developing creative, ethical, and engaged citizens. The current context shows us the value of moving past the world "as is" and towards the world "as it becomes" and as it "could be." There is no denying of the fact that the students of today will face a different landscape of problems and solutions in a few short years. Gearing education towards the present, even while acknowledging this present as dynamic, is not enough. What we need is a multiplicity of pedagogies matching a multiplicity of known and unknown possible futures (Bruner 2009).

What would it mean to take on board our own assumptions about the world – e.g., that it is complex, multifaceted, open-ended, unpredictable, ambiguous, continuously changing – and infuse it into educational experiences inside and outside the classroom? How can we move our focus from

actuality to possibility in a way that doesn't lose track of "what is" but considers it through the lenses of "what is not," "what is to come," and "what can be brought about"? Could we envision new forms of pedagogy that let go of past certainties and the need to plan every single educational experience and become infused, instead, with uncertainty, wonder, liminality, hope, and possibility? In this brief entry, we express confidence and hope that these new pedagogies are not only possible, they are mandatory. What we need is a better understanding of how we can bring them about; in other words, how we can turn general principles into new practices. We start here from a discussion of the possible and its relation to difference, then continue by focusing on the nature of creative experience and end with some old and new themes that are important for designing for possibility in and outside the classroom.

Possibility and Difference

Pedagogies of the possible are eminently plural and this is due to the nature of the possible itself. But what exactly is the possible? Centuries of reflection in philosophy, literary studies, and, more recently, psychology, left us with a better understanding of what the possible is not rather than what it is. Two common dichotomies dominate this field of inquiry: possible|actual and possible|impossible. Both these oppositions are problematic. The first places the category of the possible into the realm of illusion and irreality. What is possible is never fully real given that the moment it materializes, one way or another, it passes from possibility into actuality. This understanding effectively separates being from becoming and fails to grasp the fact that possibilities are shaped and, in turn, come to shape "what is." The second dichotomy assumes that the impossible closes down all possibility; and yet, imagining impossible things has long been at the heart of human existence – as reflected in utopian thinking – and, thus, served as a driver of action, not the unsurmountable obstacle it is often assumed to be.

For education, these debates are important because they lead to two main approaches to

possibility, both of them limited: rejection on the basis that schooling should focus on what is real and not teach students about illusory things, or adoption inasmuch as the possible is reserved for what is likely to happen rather than what can never happen. In either case, we are left with an impoverished curriculum that sends students back to what is fixed, actual, known, likely and, most of the time, what took place in the past. In order to develop pedagogies that invite students to explore the unknown, the uncertain, the hypothetical, the future, and even the impossible, we need a shift in perspective and a redefinition of possibility itself.

What we propose here builds on sociocultural approaches to the possible (Glăveanu 2020a) that operate with a different set of assumptions, many of them directly relevant to the work of teachers and their classroom experiences. In particular, this approach considers possibility as emerging out of difference and, as a consequence, demanding the existence of multiple ways of thinking, acting, and being. For possibilities to be sensed, anticipated, and enacted, we require an understanding of how they differ from “what is,” as well as from each other. Differences of perspective are particularly fertile for the possible as they present the person with a multitude of positions in the world and their associated points of view. And what happens with this multitude is key for how we notice and make the most of existing possibilities (or not).

Educational settings are, by definition, the seat of difference and possibility. There is intrinsic diversity within any group of people, for as homogenous as their members might seem from a given standpoint. What amplifies this diversity is the fact that all the actors in education interact with each other, exchanging, adopting, challenging, and proposing new perspectives. These dialogues of perspective substantiate the possible in each classroom, if and when there is genuine openness to the point of view and the experience of other people (Glăveanu and Beghetto 2017). For as straightforward as this precondition of possibility sounds, it is often the most difficult to satisfy. This is because most classrooms are dominated by “Pedagogies of Sameness” rather than difference and possibility. Providing the same kind of feedback, the same resources, the

same level of support, the same tests, using the same scales, matching students with the same careers as before, etc., this principle is antithetic to the use of emergent differences to create, to envision multiple futures, and to learn with and from others.

Experiences of difference – especially radical differences – can be unsettling. And yet, it is precisely in this moment of disbalance, of failing to grasp the perspective of another, of starting to question the taken for granted, that possibility “irrupts” within our experience and, in doing so, transforms it altogether. In education, these moments are often described as creative experiences and, while possibility cannot be reduced to creativity, the building blocks of a creative experience reflect well the commitment to difference, uncertainty, and the future that characterizes what we call here Pedagogies of the Possible (see also Glăveanu 2020a).

Markers of Creative Experience

There is an old assumption in the field of creativity studies that schooling tends to “kill” – or at least harm – creative expression (even if empirical studies debunk this view; Gajda et al. 2017). Repeated calls have been formulated over the years to foster creativity in the classroom and considerable progress has already been made in this direction. We are witnessing today a gradual but sustained questioning of (and in some cases, move away from) standardization and towards personalized education, from formal schooling to lifewide learning, and from memorization to creative expression. With respect to the latter, important distinctions have been made between “teaching creativity,” “teaching for creativity,” and “teaching creatively” (Beghetto 2017b). There is increased awareness of the fact that creativity is more than a cognitive skill; it is a way of being, a manner of approaching problems and life itself that is flexible, nonlinear, and open to the future. However, while cultivating creative abilities and associated mindsets is high on today’s agenda in education, the assumption remains that there are times and places for “creating” and times

and places for “learning” and that a focus on creativity is valid only inasmuch as it helps teachers and students reach pedagogical goals set in advance. In other words, creativity is allowed in the classroom as long as it serves a purpose and that purpose is to attain predetermined learning outcomes.

What hinders creative expression and, with it, the exploration of new possibilities in education takes us back to the dominance of Pedagogies of Sameness. They are reinforced by the fact that, even when creativity is placed in the curriculum, the focus is on creative outcomes (e.g., evaluating their novelty, originality, value, surprise element) rather than creative processes and, especially, the kind of possibility-based relations creativity helps us establish with ourselves, with other people, and with the world. Recently, we advanced the notion of creative experience as essential for understanding creativity. We defined it as an experience specific for those novel person–world encounters characterized by open-endedness, nonlinearity, pluri-perspectives, and future-orientation (Glăveanu and Beghetto 2020).

Taking these in turn, open-endedness captures the fact that, in creative forms of education, both teachers and students alike are interested to explore topics and ideas they don’t have clear or final ideas about and to learn from each other in the process. Being open in the classroom means asking more “unknown questions” rather than questions the teacher, for instance, knows the answer to and guides the student towards. It also means accepting *not knowing* as a productive, generative state rather than something that has to be eliminated or dealt with. Nonlinearity captures the dynamic aspect of teaching and learning processes that never fully progress from a pre-determined point to another. Even in the most constrained and well-rehearsed episodes of teaching, the meaning being produced by teacher and/or students follows a nonlinear path – there is always room for serendipitous encounters. This is even more the case within classrooms that take a Pedagogies of the Possible approach to cultivating creative experience. Here, lesson un-planning (Beghetto 2017a) is used as a tool to introduce indeterminacy within an otherwise organized

performance. Indeed, it is not the case of throwing all rules out the window; in the end, possibility and creativity both need constraints. Pluri-perspectivism complements these two markers by revealing the possible within everyday classroom interactions. It is because each person holds a multitude of perspectives and shares at least some of them with others that there is the potential for emergence and novelty. Being able to listen to the point of views of others, and respect it as a perspective in its own right (even without agreeing to it), is a necessary (not sufficient) condition of creative experience. Last but not least, pedagogies of the possible orient all the participants in the educational system towards the possible rather than anchoring them in the past alone. The mission of education is not primarily to transmit old knowledge, but to transform this knowledge for the purposes of the present and in view of open-ended, multiple, and essentially unknown futures.

Old and New Themes Within Pedagogies of the Possible

The Pedagogies of the Possible are themselves an emergent category, one that captures a polyphony of voices and perspectives. Within them, it is not only the pedagogies that are plural, but also the possibilities. Eight possibilities for educators are briefly discussed below: not knowing, failure, uncertainty, movement, anticipation, dialogue, care, and responsibility. The first four represent phenomena that are typically less encouraged in the classroom, while the second four capture emerging points of focus in educational theory and practice.

Possibilities of Not Knowing

Typically, educational efforts are focused primarily on helping students know more and to gain certain and valid knowledge. Although understanding the known is an important pedagogical goal as it fuels creative learning and development (Beghetto 2019), a predominant focus on the known is problematic. This is because an overly narrow focus on the already-known ignores the intrinsic possibilities embedded within

experiences of “not knowing” for both teachers and students. Building on contemporary theories of wonder (Glăveanu 2020b; Schinkel 2020), we argue for the generative power of “dwelling in the unknown” (Heidegger 1962), the creative potential that opens from “sitting with uncertainty” (Beghetto 2016) and related practices that help us defamiliarize the known. The power to make the familiar unfamiliar helps re-present the world for teachers and students alike, to engage in constructive doubt and practices of questioning. This type of inquiry has long historical roots – going back to the *maieutic* method of Socrates – and holds the potential of uncovering new horizons for twenty-first century education, opening it up to multiple, undetermined outcomes and futures.

Possibilities of Failure

Just like not knowing, failure is discouraged in education or, at best, contained to small exercises students are meant to learn from (principally learn the correct answers and, thus, how to avoid future failure). This approach discourages risk-taking and creative exploration. More than this, it prevents students from learning from experience (Dewey 1934) and from seeing failures as new sets of possibilities made apparent by the encounter with what is – or seems to be – impossible. In this way, exploring and sharing narratives of our own and others’ failures opens new horizons for learning and growth (Beghetto *in press*). This exploration of the boundaries of possibility represents a key engine of growth and development because the act of trying out ideas and actions is a rare opportunity to understand oneself and the world. Experiencing different types of possibility-enhancing failures expands the repertoire of methods for those educators who have the courage to teach and learn creatively (Beghetto 2019).

Possibilities of Anticipation

It is often claimed that education should prepare students for the world of tomorrow and for jobs and challenges that have not yet emerged or been invented. And yet, the way schooling is done prioritizes the past over the present and future – it is the transmission of accumulated knowledge that has precedence, occasionally with

applications to the problems of today. We are in dire need of exploring a new set of possibilities in education enabled by our capacity to anticipate (Poli 2017) and, in doing so, to build multiple, open futures. An education geared toward the future needs to go beyond forecasting exercises that are chained to the past through pre-established causal links and that help students ask “what is most likely to happen.” In exchange, it should cultivate anticipations that lead to foresight or the abductive process of imagining what is to come in complex and nonlinear ways (Glăveanu and Beghetto 2020).

Possibilities of Dialogue

Dialogue has long been recognized as pivotal in education and studied in terms of exchanges between teachers and students, on the one hand, and students and students, on the other. The focus is often on designing dialogues that foster the transmission and reproduction of knowledge. However, there is more to dialogue than reaching a common understanding of things. In fact, from a dialogical point of view, the possibilities of dialogue rest precisely in the fact that there is always an element of new, surprising, or unpredictable insight associated with such exchanges (Bakhtin 1984; Matusov 2020). Dialogue also rests on perspective-taking and our human propensity to understand the minds of others. We need a more sustained exploration of the way in which dialogues of perspective construct spaces of emergence and possibility in education and how these spaces, in turn, resonate with wider dialogues within society and the alignment and clashes that substantiate them (Glăveanu 2020a).

Possibilities of Care

Another relatively new venue of research in education has to do with affect and what is becoming known as the “affective turn” in this domain (Dernikos et al. 2020). The discussion of emotions certainly has older roots, going back to an interest in self-esteem at school, but what we are becoming more and more aware of is the need to cultivate empathy and compassion in students and develop their emotional engagement with the world and with other people. The possibilities of

care (a notion discussed by Heidegger 1962, in terms of presence or *Being-there*) transcend any quick, transactional affective states and reveal the importance of opening oneself to the experience of others as part of one's own being-in-the-world. This necessarily means accepting a degree of vulnerability that helps teachers and students make the most of momentary, "creative openings" in education (Beghetto 2017b).

Possibilities of Uncertainty

Similar to not knowing, uncertainty is not generally welcomed in the classroom. In fact, it is often more difficult to see the learning opportunities embedded in the latter compared to the former. This is because uncertainty is associated with lack of control and education explicitly places teachers in a position of power and control, one from which they can develop student's ability to replace old uncertainties with newly found certainties. This misses an important and generative space of possibility (Beghetto 2020) in which certainties can be questioned once again and the uncertain confidently explored. Different practical tools have been recently proposed for educators who are willing to expand these spaces without giving up all structure in the form of lesson un-planning and structured uncertainty (Beghetto 2017c, 2019). These techniques are based on the principle of cultivating possibilities within otherwise planned lessons and fully exploring their potential for learning, creativity, and development.

Possibilities of Movement

Acting upon most of the possibilities outlined in this encyclopedia depends on movement, either physical or symbolic/psychological. In turn, mobility depends on acts of repositioning and especially position exchange (Gillespie and Martin 2014). Through the latter, we get to occupy, even if temporarily, the position of the other and, thus, grasp his or her perspective. This contributes to the dialogues of perspective mentioned before and the new possibilities discovered through them (Glăveanu 2020c). We need to add a new, embodied dimension to these dialogues by focusing on the movements that underpin them.

As argued in recent decades within the new mobilities paradigm (Urry 2016), movement is an integral part of human existence and action, and this certainly applies to the domain of education. We should thus examine more closely all the ways in which movements both open up as well as close down possibilities while preventing us from being stuck within singular positions in and perspectives on the world.

Possibilities of Responsibility

Pedagogies of the possible concern much more than what happens within the walls of the classroom – they connect us to society and the power dynamic that enhances possibilities for some groups while diminishing them for others. As such, it is imperative for twenty-first century education to raise key ethical questions and issues that advance a social and environmental agenda preparing students for an engaged life as citizens (Glăveanu 2015, 2017). The possibilities of responsibility connect us to the world outside of the school and especially the struggle of different marginalized communities to reimagine society. Developing students' capacity for utopian thinking and for hope (Solnit 2016) is crucial for the kind of social transformation that starts with education and fundamentally shapes it. In the end, Pedagogies of the Possible are both enablers of and enabled by "societies of the possible" (Glăveanu 2020a) and their commitment to plurality, alterity, and to an open future. Moreover, enacting new pedagogies and projects that go beyond the walls of schools and classrooms entails an inherent responsibility of anticipating and monitoring the potential unintended consequences of innovative efforts.

Final Thoughts on Designing for Possibility in Education

Pedagogies of the Possible represents a radical new way of looking at education that is guided by the themes discussed above and by the hope and confidence that we can create practices of schooling that not only mirror the changing world of today but understand and lead this

change towards a more just, inclusive, and sustainable future. New pedagogies are emerging before our eyes, animated by a need to correct racial and social injustices, confront the long shadows of colonialism, tackle the swiftly advancing climate emergency, and adapt to a pandemic and post-pandemic social and educational environment. What these pedagogies have in common, we believe, is a focus on the possible as an emancipatory, participative, and emergent category. The possible is not the opposite of the real but its companion and engaging with it is the true marker of human existence and human society. In this sense, Pedagogies of the Possible aim to rekindle the core feature of pedagogy by inviting us to acknowledge the potential that lies within moments of rupture, of uncertainty, of not knowing and to cultivate this potential within all classrooms, on a global scale, in the learning and lives of all people.

Technology, University of Bergen, Bergen,
Norway

Abstract

This entry focuses on the notion of perspective as it is used in philosophy and psychology. From a pragmatist standpoint, I conceptualize perspectives as action-based relations with the world and, in doing so, respond to both accusations of skepticism and relativism usually addressed to perspectival accounts of knowledge, truth, and reality. In fact, following Mead's perspectival realism, I propose here that perspectives orient our thinking and action and, through this, help us discover new possibilities for both. After a brief introduction that discusses different meanings of the word perspective, I move on to describe an action-based account of perspectives and, with its help, review some important debates around perspectivism as a school of thought. In the end, the entry briefly outlines a perspectival theory of the possible that not only considers perspectives essential for our behavior and knowledge but also indispensable for becoming aware of and exploring new possibilities.

Keywords

Perspective · Perspectivism · Position ·
Action · Pragmatism · Possibility

Introduction

The notion of perspective is commonly used in a range of disciplines, including art, philosophy, and psychology, as well as often referred to in everyday language. For instance, we can ask others to see things “from our perspective” or “our point of view” and be asked to do the same in return (Kaipainen and Hautamäki 2015). In art,

perspective is employed to represent three-dimensional objects on a two-dimensional surface and, in this way, to add space and depth – in other words, realism – to a picture plane. Interestingly, the rules of perspective in Western art, rules that we nowadays take for granted, have been developed during the Renaissance, in Florence, in the early 1400s (see Boddy-Evans 2019).

And yet, this infusion of realism into paintings through the use of perspectival techniques might seem at first to be at odds with how perspectives are employed in philosophy and psychology to problematize our very understanding of **reality**. Starting from visual perception, where it soon becomes clear that we all perceive the world from a certain position (and, hence, develop unique visual perspectives on it), the notion came to designate our relationship to knowledge in general. But this transition between perception and knowledge also obscured different meanings of the word perspective:

When we want to discuss how things appear to us without committing ourselves to the claim what we have is knowledge, we preface our statement with ‘from my perspective;’ if we want to expand or question our preconceptions we say we need to ‘approach things from a different perspective;’ when we want to get a better idea of how things are in relation to other things, we might say we need to ‘put things into perspective.’ The concept of the perspective is given a metaphorical life that so exceeds its application in visual language that we scarcely notice the inconsistency of its use. In the first statement, a perspective is a personal thing that has little to do with how things actually are and more to do with how they are interpreted. In the second, a perspective is malleable, adaptable, and adoptable, and this mutability can reveal new aspects of the way things are. On the third, we are confronted with a specific perspective that *is* the way things are – putting things into perspective is to view them as they truly are relative to all other things and relations. (Raff 2018, p. 4)

Most often, the use of perspective in philosophy and psychology makes reference to the first two meanings, depicting knowledge as partial and malleable. This has often been interpreted as a denial of either reality or, at least, of the possibility of grasping the final or absolute truth about it. If our perspective is one among many, how can we be sure that it is the correct one? And, if things can

always be approached from multiple perspectives, then can true knowledge ever be possible? The first question fuels skepticism, the second one relativism. The third meaning in the quote above uses the word perspective to actually negate other perspectival accounts – the possibility to adopt an aperspectival point of view, a view from nowhere leading to an absolute conception of the world (Nielsen 1993).

And yet, as I will argue here following pragmatist scholarship, the fact that our knowledge and experience are perspectival doesn't need to deny reality or follow an "everything goes" mentality that is, worryingly, so aptly used today by advocates of **post-truth** in politics and society. Holding a perspective doesn't distort the world but relates us to it in a specific manner. In the words of G. H. Mead (1938, p. 115), "the perspective is the world in its relationship to the individual and the individual in his relationship to the world". Perspectives are, essentially, relationships we establish with the "something" that is their object, their "aboutness". A perspective, thus, is not forged in the mind as an abstract idea, but in the process of acting in and on the world and interacting with others. This is a crucial point to make and, as we shall see here, one that can help us solve the paradoxes of perspectivism. In the end, it is this relational and action-based nature of perspectives that makes them essential for opening up the possible in our existence. Moving between perspectives, placing them in dialogue and "playing" with them (in the way **Magritte** and the cubists did in art) both intrigues and delights us for a reason. Relating to the world from multiple perspectives, I argue towards the end, radically expands our possibilities for thinking about it and acting on it; it is, ultimately, what makes the possible *possible*.

Perspectives and Action

Perspectives, as mentioned above, are part of a visual type of vocabulary. To hold a perspective, in psychology and in art, typically means to have a certain viewpoint into a scene or, more broadly, to have a point of view. But a point of view requires

being in a certain position (i.e., the point) from where we look at the world. If we are to extrapolate from this, the positions we occupy in the world not only physical but also social and symbolic. We are embodied beings who, at all times, perceive only a small fraction of our environment through our senses. These are the perceptual perspectives (including visual ones) we develop from being in a certain place at a certain time. We are also socially positioned by occupying different roles in different situations or even in one and the same situation. For example, doctors and patients, parents and children, speakers and listeners, etc. Each one of these social roles affords us unique perspectives in a situation guided by specific concerns, interests, and types of knowledge. For instance, when trying to find a good toy, a child might very well have a different perspective on what "good" means compared to a parent. This means that their conceptual or symbolic perspectives differ.

What is useful about positions is not only to understand that each perspective we develop relates back to a kind of position we occupy in the world, but that we can and do change positions (physically we move, socially we exchange roles, etc.; see also ► "**Position Exchange Theory**") and, as such, can shift our perspective, including take the perspective of another person. It is because of this fundamental capacity that we are never "trapped" within singular or unitary perspectives but compelled to diversify, compare, and integrate perspectives in our interactions with others and the material world. This kind of interactivity is the premise behind the pragmatist approach to perspectives. In the words of Jack Martin (2006, p. 67), "a perspective is an orientation to an environment that is associated with acting within that environment. Perspectives emerge out of activity and enable increasingly complex, differentiated, and abstracted forms of activity. Because the human world is a social world, all perspectives arise and are employed within interpersonal interactivity".

Saying that a perspective orients us towards our environment means that it basically orients our action. It is in the course of action (and interaction) that we get to occupy different positions

and have a chance to vary our perspectives that, in turn, guide what we think and what we do in a particular situation. To take a simple example, during episodes of **play**, children get to adopt different positions, like thief and policeman, and consequently enact the perspective of a thief or a policeman within the play situation. The child who plays thief is consequently looking for any opportunities for wrongdoing and the child playing policeman tries to apprehend the thief. These different perspectives open up for them different action possibilities (Martin and Gillespie 2010): suddenly a piece of wood can become a pretend weapon and a piece of thread can be used to make a trap. Needless to say, without taking on these roles (or positions) within play and thus enacting their perspectives, the children's actions wouldn't have used any of these **affordances**. It is because we adopt certain perspectives in a situation that we get to experience a certain set of possibilities within it. As our positions and perspectives change, so do these possibilities. An exploration of the possible, as I will argue at the end of this entry, requires us to adopt various positions in the world, experience their perspectives, and place them in dialogue.

Many of these ideas go back to the seminal work of **George Herbert Mead** (1938), who famously associated taking the perspective of the other with the emergence of the human self. In his view, it is only when we become able to step outside of our position and understand ourselves from the standpoint of an other – effectively grasping this other's perspective on our action – that we become self-reflective. Without this kind of **reflection**, the self never gets to take any distance from his or her egocentric view of the world; in other words, from his or her individual position and perspective. It is in interaction with others that we open ourselves to new positions and new perspectives and, in the process, become able to simultaneously experience being in one's own and another's perspective (Martin 2006, p. 69). To return to the example of children's play, in order to coordinate their actions as thief and policeman, each one of the players needs to be aware of the perspective of the other while enacting his or her own

perspective. The thief wouldn't know where to hide without an understanding of the perspective of the policeman, i.e., where a policeman would look for him or her. This is essential for any social interaction. When speaking to others, if we had no possibility to grasp their perspective and relate it to our own, we wouldn't know what to say, how to say it, when to continue, and when to stop.

This brings us to the important function of *distantiation* afforded by adopting multiple perspectives on the world. In essence, as Martin and Gillespie (2010) argue, most organisms in the natural world are contained to singular perspectives because they have only one type of relation to things in the world (e.g., cows cannot relate to grass as anything other than food). Humans, on the other hand, have a flexible relation to the world precisely because, through their action, they can “take distance” from their position, exchange positions, and alternate between perspectives. And it is by coordinating perspectives that we develop as “psychological beings with self-understanding, and purposeful, agentic capability” (p. 256).

Perspectivism: Approaches and Debates

If in psychology action-based approaches to perspective prove to be very fertile for our understanding self and **agency**, in philosophy perspectival accounts have been formulated mainly to address issues related to knowledge and truth (see, for example, the recent volume edited by Massimi and McCoy 2020). And it is in these latter areas that perspectivism has proven to be highly controversial in particular due the accusation that it ends up denying reality by fostering an extreme form of relativism. In this section, I will briefly review this debate and the numerous attempts made in recent decades to reunite perspectivism with realism. I will use the pragmatism account described before to contribute to this defense of perspectivism and try to debunk important misconceptions about perspectives and about the nature of our knowledge more generally.

First, let's start with a description of metaphysical perspectivism:

Metaphysical perspectivism can be succinctly defined as the view that all being is perspectival. This means that the world is made up of perspectives upon perspectives and perspectives within perspectives. There is nothing more ultimate or fundamental about it than these perspectives and their constituents, in their convergences and divergences. (...) It follows that, not only is there no absolute standpoint from which the world can be comprehended as a whole, there also can be no such thing as an all-encompassing totality or unity of the world. For metaphysical perspectivists, there is considerable truth in claiming that there are as many worlds as there are perspectives. At the very least, such thinkers will insist that ‘the world’ – if we wish to retain that convenient locution – exhibits pervasive, ever-evolving disunity as well as unity in its perspectival character. (Crosby 2007, p. 57)

The short passage above makes the connection between a perspectival ontology and a perspectival epistemology and its consequences. If ontologically we live perspectival lives, bound as we are by our position in the world and its unique and situated character, then our knowledge of the world is necessarily partial and situated. This claim raises a serious challenge to our centuries old understanding of truth as that knowledge that corresponds to how reality is. If we cannot fully grasp reality, then can we know any ultimate truth about it? In fact, advocates of an absolute truth must, implicitly or explicitly, support an aperspectival, “view from nowhere” (or “God’s view”) approach to knowledge in which there is a way to escape limited perspectives and develop an all-encompassing one that, as we see from our discussion here, would go against the very idea of a perspective. The difficulty is that, while we can see how many areas of life and certain disciplines are highly perspectival (e.g., interpreting a piece of art or debating the meaning of democracy), others, especially in the natural sciences, are founded on the very assumption of objectivity and the quest for an ultimate truth about how reality “is”. Hard sciences might accept that we develop partial and situated perspectives but then strive precisely to overcome them.

A strong form of perspectivism, however, would say that this scientific goal is in vain. That we never escape the perspectival nature of our

knowledge and, more than this, that there is no ultimate truth to discover about the world. This position opened up perspectivism as a school of thought to accusations of fueling skepticism and relativism, that it aims to replace facts with interpretations (see Raff 2018). According to this criticism, perspectives not only limit our understanding but distort it. And yet, different authors came to claim that, whatever version of perspectivism one adopts, there is always a possibility to reconcile it with realism (see, for instance, Votsis 2012). Some of these solutions propose that, if perspectives always give us partial knowledge, then adopting multiple perspectives or putting them in relation to each other would get us closer to absolute knowledge. However, postulating the former violates already a core assumption of (strong) perspectivism. Is it possible to respect the fact that we can make truth claims about the world while fully adopting a perspectival ontology and epistemology?

To answer this question, we must return to the work of Friedrich Nietzsche, the scholar who is often considered the father of perspectivism. While the notion that our knowledge is perspectival predates Nietzsche and goes back, for example, to pre-Socratics like Protagoras, he most famously denounced objectivity using a clearly perspectival approach. In the *Genealogy of Morals*, Nietzsche (1956) claimed that, if we want to see differently than we need to embrace different perspectives, to use “different eyes.” Interesting to note, Nietzsche’s own thinking about truth, knowledge, and reality had evolved over time. If at first, he found the true world unattainable or unattained, he later moved on to questioning the existence of a true world and its usefulness, ending up by rejecting it altogether. In one of the most cited paragraphs of his work, Nietzsche writes:

Henceforth, my dear philosophers, let us be on guard against the dangerous old conceptual fiction that posited a ‘pure, will-less, painless, timeless knowing subject’; let us guard against the snares of such contradictory concepts as ‘pure reason’, ‘absolute spirituality’, ‘knowledge in itself’: these always demand that we should think of an eye that is completely unthinkable, an eye turned in no particular direction, in which the active and

interpreting forces, through which alone seeing becomes seeing *something*, are supposed to be lacking; these always demand of the eye an absurdity and a nonsense. There is *only* a perspective seeing, *only* a perspective ‘knowing’; and the *more* affects we allow to speak about one thing, the *more* eyes, different eyes, we can use to observe one thing, the more complete will our ‘concept’ of this thing, our ‘objectivity’ be. But to eliminate the will altogether, to suspend each and every affect, supposing we were capable of this—what would that mean but to *castrate* the intellect? (Nietzsche 1956, GM, III, 12)

What the passage above makes clear is the fact Nietzsche believed, much like the pragmatists that came after him, that perspectives relate us to world in a much deeper way that perception (and his own metaphor of “seeing”) suggests. Moreover, that looking for a “view from nowhere” is absurd and actually damaging to our knowledge and understanding of the world. By rejecting the existence of absolute, disinterested knowledge, Nietzsche actually dispenses with skepticism because beliefs can no longer be falsified against “what is.” Moreover, it is a mistake to believe that, in doing this, the German philosopher gave a free hand to extreme relativism in which there is no basis anymore for wrong or inaccurate perspectives. In fact, Nietzsche doesn’t completely relinquish truth claims and he repeatedly considered specific perspectives to be false. An example of the latter is the theologian’s assertion of truth, when in fact his or her perspective is clouded by resentment and upheld by an instinct of self-preservation. Even if Nietzsche didn’t believe in any ultimate truth, he did find some perspectives “truer” than others (see Jonas and Nakazawa 2008).

The reception of perspectivism has been mixed to say the least. Pointing to the paradox at the heart of perspectivism, Reginster (2001) for instance wonders how Nietzsche himself was able to make any claims at all if no perspective is absolutely true. But, as we saw from the discussion above, many of his critics are misreading Nietzsche. Perspectivism is not opposed to realism and the idea of truth, it just gives them a new basis compared to the old correspondence theory and Kant’s thing-in-

itself. Massimi (2016), for example, identifies no less than four types of perspectival truth. She advocates in particular for a “success from within” approach in which a perspective performs adequately with respect to the standards appropriate to its epistemic context when assessed from another point of view or another perspective. Different forms of perspectival realism came to prominence in recent years and a wider understanding about perspectivism emerged that “rather than making knowledge meaningless through distorting the interpretations made by cognizing subjects, perspectives enable the cognitive relation to occur, and have a structural role in the relation between a cognizing subject and objects of their cognition” (Raff 2018, p. 2).

This understanding takes us back to action-based accounts of perspectives specific for pragmatism. In this approach, briefly outlined in the previous section, perspectives enable the cognitive relation with our world to occur and much more. It is not only knowledge, but the very existence of a human self that is at stake. Instead of being distortions of reality, perspectives give us access to it and also help us *transform* it. Because one fact that is obscured by a knowledge only focus, but revealed by an action one when it comes to perspectives, is that thinking and acting in the world are deeply interrelated. There is no knowledge possible outside of action (see Piaget 2005). Perspectives not only reflect the world back to us; they help us change it in the course of our interaction with other people and their perspectives. This is how, for example, Davey’s (1990) point that “whereas perspectivism initially offers the interpreting subject access to a plurality of worlds, it in fact ends up asserting a multiplicity of self-enclosed worlds between which hermeneutic transfer is impossible” (p. 277) becomes invalid. In a pragmatist sense, perspectives are *interactive* in both their origin and dynamic and far from self-enclosed universes. After all, they capture the truth about the interconnected worlds we live in. And they also reveal what is possible.

Perspectives and the Possible

From a pragmatist, neo-Meadean standpoint (for details, see Gillespie 2005; Martin 2007), positions and perspective are interchangeable and interdependent with each other. Indeed, instead of having in mind an abstract individual trying to figure out the world on his or her own, pragmatism proposes a view of agentic people who move between positions, exchange perspectives, and, in this way, construct dynamic spaces of intersubjectivity. It is due to the fact that we can come to an agreement about certain perspectives on reality, including by taking the perspective of others, that we judge some perspectives as more useful, complete, or “truthful” than others. But it is also the case that it is the gaps and tensions between perspectives that open up new spaces of possibility for self and others.

The theory of the possible I have formulated over the past years (see Glăveanu 2018, *in press*) starts in fact from the notion of perspective or, more precisely, from differences in perspective. The premise of this theory is simple: to perceive our relation with the world (including our knowledge of it) as a perspective means to understand it also as *one among many*. The fact that I hold a perspective basically means that another person can and does hold another one, likely on the same issue. This is the case with both visual (or, more broadly, perceptual) perspectives, given that we all necessarily occupy different physical positions in the world, and conceptual perspectives, where people can come to different conclusions because of the difference in their social and psychological positioning (e.g., their life history, interests and concerns, existing knowledge and so on). To be aware of one’s relation to the world as a perspective on it means, therefore, to become aware that more is possible in the way we think and act on the world when adopting a new perspective. And it is this ever-present possibility of repositioning oneself, ultimately defining our existence as social beings, that compels us not only to have a sense of the possible but also actively explore new possibilities by placing different perspectives in dialogue.

Martin and Gillespie (2010) saw the dynamic captured here as essential for agency and emergence. I postulate it as also fundamental for our relation to the possible. The two issues are intimately related since, as the two authors note, “agentive activity emerges” at the intersection of “an expanded matrix of actual and imaginal perspectives and possibilities” (p. 259). The fact that we are not trapped within singular perspectives (or types of relation) to the world means that we can always approach it from a new position, including the position of others that becomes internalized in the process of developing perspectival selves (see Martin 2005). Perspectival selves and worlds, as the ones imagined by Mead, are selves and worlds of the possible. Conversely, worlds in which there is only one ultimate or absolute perspective – which, as explained here, means that other perspectives are useless, and that the one perspective effectively loses its status as a perspective – are those in which there are no new possibilities to explore, worlds devoid of emergence and **novelty**.

Summary

The notion of perspective is widely used in art and the social sciences. However, these multiple uses have different histories and hide different meanings. This is how perspectivism as a school of thought encompasses a multitude of possible interpretations about the nature of truth and of what is real. To describe perspectives as illusory mental constructions that distort our understanding of reality is, as shown here, a misrepresentation. Perspectives are not mental representations but action-based relations that we establish with the world from our physical, social, and symbolic position within it. They guide action and are discovered and transformed in the course of action and especially inter-action. It is because we live in a world populated by others, with their own positions in and perspectives on reality, that we get to complexify our own knowledge, including of oneself. Perspectivism, from the pre-Socratics to Nietzsche and to the neo-Meadeans of today, doesn’t promote an “anything goes” philosophy,

far from it. On the contrary, it grounds truth and knowledge in action and it considers not only how we get to know but also to change our shared reality. This is why, nowadays, it has a series of promoters who support its application including in teaching the natural sciences (see Pearce 2013).

For the purpose of this Encyclopedia, I added a new dimension to current discussions of perspectives, action, and knowledge, that of the possible. My argument has been that perspectival worlds are also words of possibility and that understanding one's relation to the world as "one among many" is crucial for making us aware of an expended field of possibilities. This is how, for instance, acts of repositioning and **perspective-taking** become essential for engaging with the possible, joining other processes discussed in these pages such as **imagination**, **counterfactual thinking**, or **wondering**. I would even go as far as to propose that the notion of perspective, as put forward here, underpins most of these other processes and can give us a solid basis for developing a general theory of the possible, should this endeavour ever be considered useful.

²Department of Psychological and Behavioural Science, LSE, London, UK

Abstract

Perspective-taking is a routine and seemingly intuitive part of our everyday social life, yet at the same time, it is a difficult phenomenon to describe, conceptualize, and enhance. This entry considers (1) ways of conceptualizing the primary elements of perspective-taking; (2) reframing perspective-taking as an interactional achievement rather than a purely cognitive skill of the individual; and (3) the relationship between perspective-taking and our ability to imagine possible futures.

Keywords

Perspective-taking · Dialogism · Theory of mind · Double empathy · Subject · Other · Object · Mediator · Context · Time

Definition

Perspective-taking is a term that has been used variously across the social sciences to refer to the process of imagining other points of view. It is a routine and intuitive part of everyday life because being able to infer and predict the behavior and intentions of others increases one's own opportunity to coordinate meaningful action and establish shared understanding (Tomasello et al. 2005). It is also inherently fascinating, as evidenced by narrative genres which are built on the story of how characters interpret and misinterpret each other's goals and intentions (e.g., Iago manipulating Othello, resulting in the mistaken perception that Desdemona is unfaithful). Trying to imagine a social world without perspective-taking reveals how fundamental it is to our sense of reality. Without perspective-taking, humans would be

unable to share stories, enjoy jokes, play team games, or form groups with dynamic organization because such groups are organized through understanding that group members have distinct and potentially unique roles and responsibilities vis-à-vis each other and that all other group members are, to some extent, aware of these different roles. Communication would lose the ability to use symbols (be they words or gestures) because their use is contingent on a shared understanding of its meaning to others (Farr and Rommetveit 1995; Mead 1922). Indeed, perspective-taking underscores wider metacognitive abilities, because understanding one's own thoughts and feelings requires the ability to view one's own position from the perspective of an outsider (Gillespie 2005; Mead 1925). Thus, social interaction, without perspective-taking, would reduce humans to a stimulus-response relationship with each other, where consensus could only ever be achieved coincidentally through behavioral alignment rather than as the result of any mental or emotional process.

Yet, despite the innate and routine presence of perspective-taking in everyday life, research on perspective-taking has revealed that it is a very difficult phenomenon to describe and measure. Different disciplines have investigated perspective-taking according to their own ontological and epistemological frameworks which have led to fragmented findings and concepts which, arguably, do not do its holistic nature justice. There are arguments about what perspective-taking is, for example, it could be considered a heuristic strategy, a cognitive module, an automatic orientation, or an interactional process (Heasman and Gillespie 2018b); how it should be measured or assessed, for example, processes of cognition, developmental trajectory, depth of conceptual knowledge, and empathy (Apperly 2012; Heasman 2018); and what causes it to fail, for example, language difficulties, implicit biases, conflicting norms, or impaired metacognitive skills (Boucher 2012; Epley et al. 2004). Consequently perspective-taking has been explored in diverse ways, for example, in the form of automated and implicit skills, such as joint-attention skills (i.e., coordinated nonverbal attention on an

object, either through eye gaze or pointing), recognizing false beliefs in others (i.e., studies of theory of mind; Wimmer and Perner 1983), evaluating implicit normative rules (Happé 1994) and mirror neurons (Gallese and Goldman 1998). Alternatively sociocultural psychological approaches have examined perspective-taking in terms of reflexive and interactional factors, including studies of introspection (Danziger 1980), folk theory (Malle 2003; McGeer 2001), social attribution (Heider and Simmel 1944), child development (Vygotsky 1986), social emotions (Shweder et al. 2008), intersubjectivity (Tomasello et al. 2005), and technology (Gillespie et al. 2018).

Conceptualization

Given the diverse term used, it is useful to identify properties that are common across research on perspective-taking. However, terminology itself poses a challenge since the language used to describe perspective-taking is often imbued with ontological assumptions. For example, using the language of “perceivers” (i.e., the entity doing the perspective-taking) and “targets” (i.e., the entity whose thoughts are being imagined) denotes the assumption that perspective-taking is a linear action, from an active perceiver to a passive target. While more automated forms of perspective-taking are amenable to such an approach (e.g., developmental studies of theory of mind which studies the acquisition of basic cognitive structures such as false belief attribution), everyday social contexts are more complex, fluid, and multilayered. In such contexts “targets” are not passive, but similarly imagining “perceivers” in return, and mutual awareness of being perceived shapes subsequent interactional moves. Moreover, this mutual awareness leads to mutual action in which each party tries to shape the perspective-taking activity of the other party, for example, through repairs (Schegloff 1992) and intersubjective effort (Corti and Gillespie 2016). A more stable terminology can be drawn from existing sociocultural frameworks which is based on the classic social psychological triangle (Zittoun et al. 2007).

Specifically, perspective-taking can be conceptualized within the triadic relation between Subject, Other, and Object.

Subject. The terminology that we use is relative to the Subject. The Subject is the focal person being examined, and it is in relation to this Subject that Others and Objects get defined. The Subject may attempt to understand the perspectives of Others within the social field (interpersonal perspective-taking) and may also attempt to see themselves from the position of others in the social field (intrapersonal perspective-taking). Subjects are not impartial perceivers of the social world but rather construct perspectives about Others based on their own norms and expectations (Epley et al. 2004). Although arguably resulting in a subjective bias where perspective-taking is always partial (Rommetveit 1974), such subjectivities are not necessarily a source of “inaccuracy.” Interlocutors are aware that others may be subjectively biased in their interpretation of the world resulting in a metacognitive dynamic that actively shapes how people present themselves and respond to Others (Ickes 1993). Subjectivity is thus a natural component of perspective-taking that is both created and navigated by subjects and should not be considered as a source of unwanted error.

Other. Others are usually humans, but they can be animals, toys, artificial agents, or entirely imagined entities. The key is that these entities, as imagined from the viewpoint of the Subject, are endowed with subjectivity, that is, with a contentful view of the social world – specifically a point of view that may be different from that of the Subject. Others may not always be other people who are immediately co-present; they can be removed third parties or even possible audiences (either at a different point in time or at a more hypothetical level, in the form of superaddressee; Bakhtin 1986). Others may also include the Subject, in terms of trying to imagine one’s own current or future thoughts and feelings. It can also involve abstract others in terms of the generalized perspective of the group (Mead 1934). Others therefore range from concrete phenomena related to the behavior of individuals to abstract phenomena related to the perceived dynamics of a group.

Object. All perspectives, whether direct (i.e., one's own perspective) or meta (i.e., taking someone else's perspective), are focused on an Object (Laing et al. 1966): this is what they are "about." Developmentally, this might be illustrated by an infant (Other) reaching for a bottle of milk (Object) which a parent (Subject) may then imagine that the child wants. Objects can include physical world phenomena (e.g., a bottle of milk) but can also include abstract phenomena, such as topics being discussed or relationships themselves. Thus, within a marriage, both parties (Subjects) may be imagining what the Other thinks in light of their perceived attitudes toward the marriage itself (Object). People's goals and intentions are another type of Object that facilitate perspective-taking. For example, in a sporting contest, the opponent's (Other's) desire to win (Object) is a principle which guides the Subject to anticipate and make predictions about the opponent's behavior in different scenarios. It is possible to have multiple Objects, and in cases of strategic communication (Habermas 1984), it is possible for subjects to conceal some Objects (e.g., an ulterior motive) for the purposes deception. An important property of Objects is that they are usually shared, either perceptually (because they are physically apparent to both parties) or conceptually (e.g., mutual awareness of a relationship).

Perspective-Taking: Dynamic and Contextual

Perspective-taking by the Subject in regard to the Other's view on some Object does not occur in an abstract Platonic realm, outside of time or space. Rather, perspective-taking is dynamic and situated. Accordingly, the Subject-Other-Object triangle needs to include mediators, context, and time.

Mediators. Mediators can be material (i.e., tools) or semiotic (i.e., language). While material tools are used to act on the physical world, semiotic mediators are used to act on the mind, or perspective, of other people (Gillespie and Zittoun 2010). Semiotic mediators facilitate the recognition and interpretation of meaningful acts. Mediators can include systems for signification, such as language, or the cultural norms that people are socialized into. Often people perspective-take

during activities – organized sets of rules and structures to guide ways for subjects to relate to each other. For example, conversation is an activity with its own implicit rules about turn-taking (Schegloff 1992) and appropriateness (Grice 1989); however, other types of activity such as ordering from a menu in a restaurant come with standard expectations associated with particular social roles that guide perspective-taking (Goffman 1958). Compare, for example, a Subject throwing a punch. During a contest a punch is recognized as a legitimate act for the purposes of winning. Outside of the activity of the round (i.e., after the round bell when fighters return to their corner), a punch is recognized as unsportsmanlike conduct for the purposes of cheating. Outside of the boxing ring altogether, a punch is recognized as an assault for the purpose of harm. Thus the shared understanding of the activity mediates the interpretation of the act (throwing a punch) which in turn shapes perceptions about the intentions of the person throwing the punch and predictions about what they will do next. Importantly it is possible for mediators to become Objects, for example, the use of a particular word in an argument can cause offence and become itself the topic of conversation.

Context. Context refers to the physical and social spaces in which perspective-taking occurs. Importantly context has two properties that can impact the nature of Subject, Other, Objects, and mediators. First, contexts are fluid and have the potential to change. For example, changing world events can quickly render some jokes (Objects) insensitive or inappropriate, which would result in negative attributions about the speaker (Other) and their language (mediators) by the audience (Subjects). Secondly, context comprises the shared assumption of what is known between Subject and Object (e.g., the historical relationship between Subjects and Others or the shared understanding about the cultural significance of particular artifacts or practices). Thus when interacting Subject and Object will consistently refer to aspects of context to "fill in" meaning (e.g., assumed shared knowledge behind marriage discussions (Garfinkel 1967)). Like mediators, it is possible for contexts themselves to become

Objects through explicit reference (e.g., via language).

Time. Time refers to the ongoing interactional dimension of perspective-taking. Although time itself is a type of context which can be made an Object through explicit reference, it is included here specifically as a separate constituent to highlight the interactional and sequential nature of perspective-taking. With each interactional behavior, be it a turn in conversation or nonverbal gesture, Subjects make salient some aspect of their thought processes with an expectation that it will elicit a particular response from Others (Farr and Rommetveit 1995). Communicative acts are therefore sequentially organized over time with Subjects in a continual process of mutually updating and shaping their perspective-taking in light of the ever-changing interactional history. Specifically, each turn in the interaction is “history making” in the sense that it becomes part of the partially shared temporal context within which subsequent turns in the interaction will obtain meaning (Bakhtin 1986). Moreover, different and multiple timescales are possible with perspective-taking. At a micro level, subjects may perspective-take in a given context with an imminent future action in mind (e.g., a “wink” from a speaker indicating that their most recent behavior has more private connotations) or a far more distal action (e.g., marriage vows which are imagined across all future selves; Adam 2013). Likewise it is possible to imagine the perspectives of historical figures through reading firsthand accounts, and it is possible to imagine the perspectives of future selves up to and beyond the point of death (Zittoun and Gillespie 2015).

Perspective-Taking as Interactional Achievement

Perspective-taking is well-documented within the field of developmental psychology, which has explored in depth the acquisition of meta-cognitive skills at different stages in childhood. How children recognize different perspectives, both perceptually (i.e., imagining differing

visual perspectives; Piaget and Inhelder 1969) and conceptually (i.e., imagining differing beliefs; Wimmer and Perner 1983), has led to the development of explanatory models of cognition (e.g., theory of mind). However cognitive models potentially overestimate the role of intellectual problem-solving (Apperly 2012; Leudar 2004) and underestimate the extent to which perspective-taking should be seen as an interactional achievement (Heasman and Gillespie 2018a).

There are two key advantages to understanding perspective-taking as an interactional achievement: its ecological validity in terms of recognizing the rich intersubjectivity which underscores the unique way in which humans make sense of each other and its utility in terms of opening up more possibilities for enhancement and intervention. Regarding the former, everyday perspective-taking involves interpreting how subtle shifts in context shape meaning for different perspectives within the social field while similarly considering how Others may be motivated to present themselves in a socially advantageous way (Goffman 1958). However a rich, situationally relevant understanding cannot be achieved through abstract reasoning alone; rather interlocutors work together to co-construct understanding (Schegloff 1992) in the flow of interaction, as evidenced through analysis of basic conversation patterns (Sacks et al. 1974). Each turn within a conversation can simultaneously act as both a response toward a prior turn and an invitation toward a future turn (Linell et al. 1988), guiding and reshaping ideas about the perspectives of others.

The interactional view has a further benefit in explaining a common property of all social interactions: the potential for misunderstandings (Ickes 1993; Laing et al. 1966). Often misunderstandings are attributed to individual parties within an interaction and are generally seen as an undesirable, inefficient, and inaccurate outcome of “failed” perspective-taking. However, misunderstandings are part of a wider intersubjective mechanism for flagging moments where interlocutors realize their perspectives are not in alignment and setting up the possibility of

realignment. This has different scales depending on the nature of the Object in question. For example, sometimes an Object may be doubtful about what has been said, and a repair sequence (Schegloff 1992), consisting minimally of three turns, helps interlocutors to flag misalignment in shared understanding and literally “repair” the source of the troubled turn. Such instances can be very quick and unconsciously automated given their routine deployment. However sometimes the Object can be much larger, such as a marriage, and interlocutors may continually interpret evidence, over many years, about whether they are in alignment about what the marriage means to both parties. In both cases, regardless of the scale of the Object, mutually recognizing the misunderstanding is the first step toward refining the approximate ideas Subjects perceive Others to hold.

Indeed, an interactional view of perspective-taking highlights how it is possible for the content of ideas to affect the process of perspective-taking. For example, autistic people have often been characterized as lacking a theory of mind (Boucher 2012) and empathy (Milton 2012) on the basis of abstract theory of mind tasks (Heasman 2018). However, non-autistic people have been shown to be biased in their interpretation of autistic adults’ perspective-taking abilities precisely because of this view (Heasman and Gillespie 2018b). Thus the very theories about autistic perspective-taking open up or constrain possibilities for perspective-taking (Hacking 1996). Moreover, autistic-to-autistic social interactions show sophisticated forms of perspective-taking not afforded by a purely cognitive view, where experimenting with the voices of film characters can lead to the creation of new language (mediator) for identifying goals (Object) and coordinating action with Others (Heasman and Gillespie 2018a) while playing video games (context). An interactional view is therefore advantageous because it recognizes, in more pragmatic terms, the processes through which people are able to achieve shared understanding, rather than attempting to focus too narrowly on qualifying the value and accuracy of a given metacognitive moment.

Possibilities Through Perspective-Taking

The interactional basis of perspective-taking outlined above extends beyond the immediate perception of co-present others to create possible futures. Humans are fundamentally future oriented, with their physiological and psychological structures geared toward practical action (James 1878). Indeed, the future is, arguably, more than the past, a driver of human action. But as an instigator of human action, it is puzzling: How can something that does not yet exist prompt human action? This can occur because the future for humans is not actually in the future; it is a semiotically constructed space of possibility in the present. Although the feelings of what is immanent can seem absolutely real, they are, nonetheless, a semiotic chimera, like the step on the stairs in the dark which one’s entire body believes to be there, only to find it absent. Thus, it is within the imagination of the future that occurs within the present where possibility exists (Gillespie 2007; Mead 1932) – as paths of possibility that enrich the perception of an otherwise pinpoint moment in time. Specifically, perspective-taking in the present intersects with, and enhances, the possible in two ways.

First, at a basic level, perspective-taking enhances the possible because so much of what will, might, or should happen depends upon other people. The world that people routinely navigate, attempt to predict, and to some extent shape is not merely a physical world; it is a social world. Having a rich mental model of what significant others (i.e., people who are consequential for one’s self) think not only makes one’s plans more likely to succeed, but it makes new plans possible. Possibilities emerge in the social world for convincing, disagreeing, teaching, joking, deceiving, and so on.

Second, at a more fundamental level, perspective-taking, one could argue, underpins human’s peculiar capacity to vividly imagine alternatives in the first place. This argument goes back to Mead (1934) who was puzzled by how humans could become an object to themselves, enabling them to tell themselves what to do – in much the same way as one might try to tell someone else

what to do. His idea was that humans “get outside themselves” by taking the perspective of significant others. Children growing up learn who they are in the eyes of others and, in this way, learn about themselves. For example, it is through other people telling the child what to do that the child eventually becomes able to tell themselves what to do; equally, it is through being appreciated that the child becomes able to appreciate themselves.

This ability to see ourselves from the outside, which occurs via perspective-taking, is, like the future, a semiotic construction. Mead was not suggesting mind-reading or that the mind can wander outside its body. Rather, perspective-taking is one of the most basic processes of the semiotic extension of the present: it expands one’s immediate here-and-now perceptual reality into the minds of others and into possible futures. While the road extending ahead and the body of the person standing there are perceptually evident, where the road leads and what the person is thinking are not perceptually evident and are thus semiotic constructions. Yet, it is in these semiotic constructions that possibility originates.

Indeed, what makes perspective-taking particularly unique for humans is the ability to go beyond purely imagining other perspectives to enacting them altogether. People can tell stories using the voices of others (Bakhtin 1986), real or imagined, which is a quality of intersubjectivity and perspective-taking made possible through language. Likewise people can readily suspend disbelief (Coleridge 2014), putting aside their own perspectives and understanding of reality in adopting a fictional worldview. The rich weaving together of subjectivities that humans can imagine, coordinate, and perform highlights why perspective-taking should be understood as an interactional ongoing process rather than a purely abstract cognitive ability for the purposes of accurate social perception.

Summary

Perspective-taking is more than a cognitive ability to impute thoughts to others. It is a process of

extending our perception of reality, both by imagining futures and reconnecting with the past, by engaging with the immediate social field, and by experimenting with the narratives of characters in fictional social fields. Humans are unique in their ability to not only imagine a range of perspectives but to enact them, adopting different voices in the dialogic construction of self.

Philosophical Health

Luis de Miranda
Uppsala University, Uppsala, Sweden

Abstract

In the last decades of the twentieth century, the first contemporary “philosophical counselors” started to appear in Europe and the USA, sometimes equating the idea of “philosophical health” with “spiritual health” or “therapy for the sane,” thus partly reviving traditions of Ancient Greek and Roman philosophical practice. Philosophical health is a state of fruitful coherence between a person's ways of thinking and speaking and their ways of acting, such that the possibilities for a sublime life are increased and the need for self- and intersubjective flourishing satisfied. One is engaging in philosophical health when one's behavior is careful (and *care-full*) in considering not only the physical or psychological individual balance but also a certain idea of what the collective and holistic good of humans and all beings on earth might be. Compared to “physical health” and “psychological health,” the idea of “philosophical health” may still appear to be new. In the twentieth century, the phrase was mostly used as a metaphor to describe sound philosophical thinking versus faulty reasoning, and the meaning has been since then extended to describe the attunement of a way of life with its conceptual evaluative grounding. A first step to understand that the idea of philosophical health is equally as important as

physical and psychological health is to recognize that any human being possesses philosophical beliefs, intellectual allegiances, and conceptual concerns, even if not yet fully explicit or compossible.

From Physical and Psychological Health to Philosophical Health

The phrase “philosophical health” was recently proposed as a complement to the ideas and practices of physical and psychological health (de Miranda 2019). Philosophical health is a state of fruitful coherence between a person's ways of thinking and speaking and their ways of acting, such that the possibilities for a sublime life are increased and the need for self-flourishing and intersubjective attunement satisfied. A philosophically healthy individual, group, system, or protocol ensures that the goals and purposes of the whole are pragmatically attuned with its highest ideals while respecting the regenerative, plural, and possibilizing future of multiple forms of life.

“Physical health,” nowadays considered self-evident, became part of modern discourse in the nineteenth century only, along the publication of manuals such as *Health Made Easy for the People, or Physical training, to Make Their Lives, in This World, Long and Happy* (Bentley 1845). The Victorian period saw a growing emphasis upon gymnastic instruction in Europe, for example, via athletic programs in public schools (Shephard 2015, 630). In Sweden, for instance, Pehr Henrik Ling, appointed fencing master at the University of Uppsala in 1805, observed that a personal program of daily exercises (fencing, horse riding, and swimming) completely restored his previously fragile health, and he was appointed in 1813 as Principal of the newly founded Royal Central Gymnastic teaching and training institute. Nowadays, the access to physical health is not a luxury for the happy few anymore; it is rather

considered to be a necessity for all. In recent decades, lifestyle-related citizen health has been increasingly monitored as a more or less universal or standard program by governments, schools, organizations, and corporations (Åkerblom 2020). Regular physical health might not be fully forced upon citizens as compulsory, yet it is certainly perceived by many as a categorical imperative, an internalized duty.

The phrase “psychological health” has slowly become a trope of our social reality since the end of the nineteenth century and the establishment of the first psychology labs in European and American universities. Janet and Freud were notoriously influential in conveying the idea of psychological healing (Larson 2017), then again applying it firstly to a few more or less privileged patients in Paris or Vienna before the notion disseminated and became a general norm. In the USA, for instance, as part of the Mental Hygiene movement that emerged in the early twentieth century, Thomas W. Salmon proposed broadening the specialty of psychiatry beyond the traditional focus on institutional care toward the societal prevention of mental illnesses (Parry 2006). By applying it to communities and social preventive programs, the National Committee for Mental Hygiene secularized and democratized the idea of psychological health in the USA (Grob 1983, 162). The slow rise in the western world of “the therapeutic culture” and the cult of the self-led to the perception of homo sapiens as “psychological man” (Rieff 2006). Psychological and mental care is today a ubiquitous licensed profession, certain forms of which are sponsored by nation-states, and “psychiatry, in the most general sense of the *psy* disciplines, has moved very powerfully into the ways in which people understand themselves, their self-technologies and into the ways in which people articulate and judge their mental states” (Rose 2020, 3).

Compared to “physical health” and “psychological health,” the idea of “philosophical health” may still appear to be a curiosity: “The first thing to notice is that there does not seem to be anything such as philosophical health, or at least we do not often speak that way” (Peterman 1992, 4). Until recently, the phrase was mostly used as a

metaphor to describe sound philosophical thinking versus faulty reasoning:

Perhaps the only discipline or method by which we can expect to improve our capacity to stand above the non-rational determinants of our philosophical beliefs and concerns is the exploration, with as much objectivity as we can muster, of the origins and antecedents of those beliefs and concerns. We *need* to know how we got where we are. The deeper the presupposition, the more valuable to our philosophical health is the activity of discovering how it was acquired. (Ayers 1985, 28)

The author of these lines, to be fair, was not much concerned with the layman, but rather with the professional and scholarly thinker, judged more or less capable of complete logical, rational, or epistemological coherence.

This somewhat professionally restricted idea of healthy thinking is often associated with Wittgenstein’s insistence on logical or linguistic consistency and his early deflationist – if not nihilistic – stance about the limited possibilities of philosophical knowledge (Gilmore 1999). However, Wittgenstein’s later insistence, in his *Investigations* (1953, §133), on the idea of philosophy as a kind of therapy that can bring peace of mind may have been instrumental in the genealogy of how the idea of philosophical health is potentially becoming democratized. According to Wittgenstein and some of his followers, we should not indulge our temptation to ignorance or cognitive somnambulism if we are to cultivate a healthy mind: “Consistency between our ways of thinking and speaking and our ways of acting eliminates, or at least reduces, the psychic tensions that acting against one’s own allegiances will cause” (Gilmore 1999, 146).

A first step to understand that the idea of philosophical health is equally as important as physical and psychological health is to recognize that any human being possesses philosophical beliefs, intellectual allegiances, and more or less rationalized concerns, often not yet fully explicit or compossible, that is theoretically and pragmatically compatible. A second step is to recognize that any form of health can be trained and improved, with the help of specialists if necessary. Between the 1960s and the 1990s, the first contemporary “philosophical counselors” started to

appear in Europe and the USA (Raabe 2001), sometimes but not always equating “philosophical health” with “spiritual health”: it was now admitted that “some people believe that good health also includes a feeling that one’s behavior is in rhythm with one’s basic values (see values). This feeling may also include a sense that life has meaning and is worthwhile” (Levy et al. 1984, 7).

A collective ideal of philosophical health may suggest that the cosmopolitical and practical idea of philosophy as democratic therapy is reborn from its Ancient Greek ashes: “The operative notion of philosophical health depends on a conception of the human good” (Peterman 1992, 18). One is individually engaging in philosophical health when one’s behavior is careful (and *care-full*) in considering not only the physical or psychological individual balance but also a certain idea of what the collective and holistic good of humans and all beings on earth might be, starting with one’s own good.

From Mental Health to Mental Heroism

Far from the popular cliché of the philosophizing person as one who renounces social life and fully represses passion or ambition, philosophy can revitalize our way of living, make it thriving, attuned and multidimensional, toward a fulfilling of one’s highest destiny. This path necessitates a form of courage that ancient philosophers compared to a heroic realization of wisdom:

The sage would thus be the man capable of living on both planes: inserted perfectly into daily life, like Pyrrho, and yet immersed in the cosmos; dedicated to the service of men, and yet perfectly free in his interior life; conscious and yet peaceful; never forgetting the unique essential; and finally, and above all, faithful to the point of heroism to the purity of moral conscience, without which life would no longer be worth living. This is what the philosopher must try to actualize [*réaliser*]. (Hadot 2014, 198 [my translation])

Such an ideal was according to Hadot best exemplified in a historical and philosophical model, Socrates. The Socratic “unique essential” is the philosophical “freedom” of the “soul” in the manifestation of its respect for a spiritual principle that guides the secular self (Hadot 1995, 161).

The Socratic ethos remains an inspiring model in our fragmented global environments, Plato’s cave still being filled with a cacophony of contradictory opinions and illusions, while digital social networks amplify the emotional contagion of humanity’s “sad passions”, to use a well-known Spinozian qualification. In order to actualize its heroic program of healthy living, philosophy needs to engage with its desire to be both spiritual and practical; yet “healthy reason” (Kant 1996, 8) cannot be only common sense: it takes extreme individual courage to think and henceforth act as independently, rationally, creatively, and coherently as possible on a daily basis. The philosophical path to healthy wisdom pertains to mental heroism also because, as exemplified by Socrates, truth is never achieved once and for all; it is a never-ending process of attunement that demands a daily effort above normality. Philosophical care is not a sinecure that can be improvised but a difficult practice, one that needs persistent theoretical and practical training.

Kant, in his *Anthropology from a pragmatic point of view*, formulated the heroic ideal of philosophical health along three maxims:

Wisdom, as the idea of a practical use of reason that is perfectly law-like, is no doubt too much to demand of human beings. But also, not even the slightest degree of wisdom can be poured into a man by others; rather he must bring it forth from himself. The precept for reaching it contains three leading maxims: (1) Think for oneself, (2) Think into the place of the other (in communication with human beings), (3) Always think consistently with oneself. (Kant 2007, 307)

Such was according to Kant the heroic ideal of the Enlightenment, also expressed in his famous imperative against mental “cowardice” and existential “immaturity”: “*sapere aude!*”, dare to know. This *dare to know* suggests a *dare to act* (or to refrain from reacting in some rational or emotional circumstances).

Despite the seductive and eminently useful aspect of formulating the ethos of philosophical heroism in the form of law-like maxims or mottos, it is however important to remember that philosophy cannot merely consist of a collection of imperatives facilitating the avoidance of being corrupted by, for example, foolishness,

cowardice, adversity, immaturity, greed, resentment, or social mimicry. Hence the need for philosophical counselors or mentors, at least until we are individually an athlete of the mind. The healthy philosophical healer is dedicated to the service of beings (inclusive of one's own being), which means that personal philosophical health goes along with a protective attitude of deep listening toward the other, notwithstanding the momentary bad influences and mental contagions that such a practice of mundane care may imply. Mental heroism is not only about being able to resist resiliently; it also about intersubjective attention and intellectual empathy: to think into the place of the other. To which one could add: Think into the place of the *Other*, by referring to that creative cosmic otherness or "creative absolute" (de Miranda 2017) that transcends anthropocentric forms of care.

Philosophical Health and the Possible

At least within the crealectic framework (de Miranda 2020), philosophical health is organically connected with the concept of the possible (see ► "[Crealectic Intelligence](#)"). Crealectic intelligence deals with processing realities and imaginaries of novelty and plurality rather than mere contradictions of binary polarities or analytic operations of known bits; its ontological core is the philosophical idea of creation understood ontologically as ubiquitous stream of ultimate possibility (Bergson 1911; Whitehead 1929, see Alfred North Whitehead; de Miranda 2017). In such context, we are not looking at reality as a static and scarce resource but as a moving actualization and interpretation among many others of an invisible source of transformative abundance, a co-creation (see creativity) in which we are dynamically engaged. Crealectic philosophical health is a program of harmonization of our collective capacity to feel, imagine, envision, realize, and co-actualize a world emerging from the cosmological source of the Real as a metaphysical and practical "possibility of possibility" (de Miranda 2020).

As was understood by existentialist philosophers, chief among them Sartre and Heidegger, the

universe is a possibilization furnace. The simultaneously immanent and transcendent – "trans-immanent" (Nancy 1996, 48) – ground of ever-emerging possibilization (*Ermöglichung*) is conceived as *opening for the making-possible* (Heidegger 1995, 364; Heidegger 1996, 244). This cosmological opening may be summarized in a simple modal formula: "It is possible," in which *It* designates the ultimate, all-encompassing being-becoming: "There is a practical consciousness, an 'I can' that underlies and precedes the reflective self-consciousness of the 'I think', but the 'I can' is given and coeval with an 'it can'" (Sinclair 2017, 191). The Surrealists for instance trusted this higher source of creation as they produced their works of art based on letting go of the obsession of controlling consciousness analytically (see surrealism). A philosophical possible originates in the holistic health process by which creative ideation as a property of the universe transmutes (into) coherent realities, regenerative environments of attuned living. Attempts at explaining how this transmutation might be brought about constitutes the very history of philosophy itself, from Plato to Hegel et al., from hermeticism to process philosophy. Philosophy is not the mere logical analysis of truth conditions, but the self-questioning process of thought regarding its own possibilizing and world-making power (see *Creating the future*), with a horizon of healthy well-being, well-doing, and well-belonging.

Current approaches to well-being can be divided into two overarching streams: subjective well-being (SWB) and philosophy as a way of life (PWL). For the sake of simplicity, we may label the first current *hedonic* and the second *eudaimonic*. Subjective well-being (Diener 1984) is often interpreted to mean "experiencing a high level of positive affect, a low level of negative affect, and a high degree of satisfaction" (Deci and Ryan 2008, 1). Because people's reports of being happy and feeling satisfaction or following pleasures in life does not imply that their life is psychically, psychologically, and philosophically balanced, the philosophical health perspective is also concerned with actualizing one's highest virtues, in the notorious spirit of what Aristotle called *eudaimonia* in Book 1 of the *Nicomachean Ethics*.

Eudaimonia is “an activity (*energeia*) that engages and deploys the excellence (*arete*) of a being capable of thought” (Moran 2018, 91). This means that human flourishing cannot be only sensual, a feeling of bliss, but needs to be accompanied by *theoria* or philosophical contemplation. For the Greeks, this meant to be inspired by a divine power (*daimon*), described by Plato in the *Republic* as “the guardian of a man’s life” or “the fulfiller of a man’s choices” (Pachoumi 2013, 49). The Greek concept of eudaimonia suggested that the connection between a human and a personal sense of the divine or the sublime is necessary in the conduct of a good life.

A relation to the sublime or metaphysical divine is indeed an important aspect of philosophical health (see sublime), but the monism of the Creative Real as a Creal of absolute possibility is sufficient to provide for an element of multiplicity and an element of transcendence that remains immanent in the manner of a potential. This is why in philosophical health practice we may refer, instead of eudaimonia, to a principle of *eudynamia*, which is based on the Greek term *dynamis* signifying power, potential, virtual, and possible: “If *eudaimonia* means to have a good relationship with our personal daimon, *eudynamia* means to have a good relationship with the possible” (de Miranda 2021).

The word *eudynamia* appeared sporadically in the German medical corpus of the first half of the eighteenth century, for example, in the encyclopedia of medicine published by Georg Friedrich Most, where it was defined as “good health, good mixture of fluids” (1836, 632). In 1843, a dictionary of Medicine published in Vienna explains the entry Eudynamia with a one-word definition: *Wohlkräftigkeit* (Müller, 120). The German compound *Wohlkräftigkeit* can be translated into English as good health, well-being, and powerfulness. *Eudynamie* was also used in French to describe the physiological and vitalist equilibrium of organic living functions. This lexicology is now more than two hundred years old and the eudynamic signifier has been since abandoned by medical language; following the creation in 2019 of the Philosophical Health International network (<https://philosophical.health>), the

philosophical practitioner Luis de Miranda proposed to resuscitate *eudynamia* from the cemetery of words in order to reinvest it with a philosophical meaning, that of a healing or attuning access to the regenerative realm of multiversal possibility. A eudynamic system or being is one that grows and unfolds in such a way that its creative relationship to the possible remains open, meaningful, and joyful.

Play

Sandra W. Russ

Department of Psychological Sciences, Case Western Reserve University, Cleveland, OH, USA

Abstract

Pretend play involves generating ideas, treating objects symbolically, and making-up and acting out stories. Expression of emotion and affective themes is an important characteristic of pretend play. Children imagine many different possibilities for events, daily problems, narratives, and fantasies. Many components of creative thought occur in pretend play and set the stage for later creative production, either in daily life or in a chosen career. All of these components contribute to the development of the ability to visualize what is possible and to act on the possible in a creative fashion. Important features of play that contribute to imagining the possible are as follows: role-playing; building scenarios; imagining; expressing feelings and affect themes; acting out problems and possible outcomes; and taking joy in playing/creating. All of these features reflect aspects of cognitive flexibility. Pretend play is important because it helps develop these cognitive and affective representations and enables the child to "play" with them and manipulate them into various combinations. This process should help cognitive flexibility develop, which, in turn, enables visualization of many different possibilities in later life. Research in the area of play and creativity is reviewed. Pretend play is a natural, built-in, venue that is self-reinforcing and universal. Further study of the processes in pretend play and how to facilitate development through play is important for future researchers.

Keywords

Pretend play · Visualizing · Cognitive flexibility · Perspective-taking · Affective processes

Play is a universal phenomenon. Children in all societies engage in play activities (Gaskins et al. 2007). Pretend play especially is important in child development. In pretend play, children imagine many different possibilities for events, daily problems, narratives, and fantasies. They pretend to be different characters and take on the perspective of different people. In most cases of pretend play, children experience positive emotions. Therefore, play is self-reinforcing. Many components of creative thought and emotion occur in pretend play and set the stage for later creative production, either in daily life or in chosen career. All of these components contribute to the development of the ability to visualize what is possible and to act on the possible in a creative fashion.

Definition of Pretend Play

First, we need to define pretend play. There are many definitions of pretend play, but a classic definition by Fein identifies the essence of pretend play. Fein defined pretend play as a symbolic behavior in which “one thing is playfully treated ‘as if’ it were something else” (1987, p. 282). The “as if” feature permits many kinds of activities to be classified as pretend play. Using a yellow block to be the sun, making a castle with magic properties, making up a story about a birthday party with dolls, and pretending to be a famous soccer player while playing the game are all examples of pretend play. Krasnor and Pepler (1980) add the features of nonlinearity, positive affect, intrinsic motivation, and flexibility of thought. Flexibility of thought was also highlighted by Sherrod and Singer (1979) when they identified two cognitive abilities unique to fantasy and pretend play. One was the ability to recombine and integrate stored images as a source of internal stimulation and to divorce these images from reality. A second ability was reinforcement for skillful recombining of images. One can infer that reinforcement was the internal positive affect that accompanied this process. The ability to manipulate internal images and ideas is a kind of cognitive flexibility important in creativity. These images are expressed in

action in pretend play, which, in turn, can give rise to other ideas and scenarios.

Fein (1987), Singer and Singer (1990), and Russ (1993, 2014) all stressed the importance of affect in pretend play. Although it is not an essential characteristic of pretend play (Thompson and Goldstein 2019), it is an important one. Fein (1987) proposed that pretense often involves feelings and emotional intensity, so that affect is often intertwined with pretend play. The manipulation of images and ideas that Sherrod and Singer (1979) thought was unique to pretend play often included affect-themes and emotion-laden content. Fein also stressed the importance of manipulating affective content. She proposed an affect symbol system that stored information about emotional events that is manipulated and worked with in pretend play. These symbols could be real or imagined experiences that are expressed in play. In fact, Fein thought that pretend play was symbolic behavior organized around emotional and motivational issues. Singer and Singer (1990) proposed a cognitive-affective framework for pretend play and thought that play was reinforcing when it permitted expression of positive affect and controlled negative affect. These theories all conclude that affective expression in play contributes to the development of cognitive flexibility, so important in creativity, which involves imagining different possibilities. Children who can express a variety of emotions in the play narrative are able to express more emotion in memories and also in creative stories (Russ and Schafer 2006). In general, they have more access to their own emotions. For example, a child who was given the opportunity to go to a gifted class in a different school wrestled with how he would feel leaving his siblings and friends behind. One can speculate that, as adults, these children will be able to utilize emotions when deciding among different possibilities. For example, in considering a retirement home, a cottage on the beach is an appealing possibility. However, the adult who can visualize and anticipate their own loneliness when they leave their lifelong friends behind will make a more informed decision than the individual who does not.

Play and Visualizing the Possible

What are the features of pretend play that enable thinking about possible future events? Important features are the following: role-playing; building scenarios; imagining; expressing feelings and affect themes; acting out problems and possible outcomes; and taking joy in playing/creating. All of these features reflect aspects of cognitive flexibility.

Role-playing occurs in many forms of pretend play, where children take on the roles of different characters. In solitary play, they might have one doll as the mother and another doll as the child. They then act out various stories. The mother scolds the child for misbehaving while the child cries or apologizes. Thus, the child is taking the perspective of both the mother and the child. In group play, children often play one character and then switch roles with one another. Research supports the association between imagination in pretend play and perspective-taking (See Russ 2014 for a review). This ability to put oneself into the shoes of the other is crucial for emotional understanding, empathy, and, on a larger scale, understanding and anticipating issues in the society. Understanding the experiences of children in poverty, being able to empathize with these children, motivates one to design social policies that ameliorate conditions of poverty.

Children make up stories in play with plots. Understanding cause and effect is important in organizing the story narrative. Children make up different endings and practice with imagining different possibilities. If we do this, then that is a consequence. In the play intervention protocol used in our studies to increase imagination in children's play, the adult asks the child to make up different endings and different plots. For example, over five 30-min sessions, the child plays out different story stems with the play facilitator. One story stem is to have a boy go to the zoo. A story stem calling for more imagination has a girl living in a city under water. A story stem pulling for feelings has a boy losing his dog and feeling sad. In that story, the child usually tries to find the dog. The play facilitator asks the child to make up different endings and feeling states. She plays

with the child, asks questions, and models pretending and expression of feelings. When this story-telling in play protocol was used with children on the autism spectrum, imagination in play increased as did emotional understanding on a different task, when compared with a control group (Doernberg et al. 2020).

Imagination occurs in pretend play. Children use fantasy and imagine different worlds, to different degrees. Root-Bernstein and Root-Bernstein (2006) studied worldplay in children. During worldplay, children create imaginary worlds and characters that continue over a period of time, sometimes for years. They found that creative giftedness in adults was associated with retrospective reports of worldplay in childhood.

In play, many children express current problems, feelings about them, and rehearse different coping strategies and outcomes. For example, children in the hospital play out stories about being ill. They might play out breaking a leg and getting a cast put on. The doctor takes the cast off and the leg is better. Today, themes of the COVID-19 virus occur in children's play. Children have been pretending to use masks and keeping distance. The play monster becomes the virus. Child therapists have used play since the 1930s to help children cope with stress and problems in living. Children can play out their fears and negative emotions in manageable bits so that fears can be extinguished and solutions to problems can be rehearsed (Singer and Singer 1990). There is research evidence that pretend play relates to coping ability. For example, children with better imagination in play could think of more solutions to problems in several different studies (Russ et al. 1999) and could use more coping strategies during a dental procedure (Christiano and Russ 1996).

The fact that pretend play usually involves positive affect and, oftentimes, joy ensures that children will return to play experiences. Because the child can control the pace of the play, even negative themes in play are experienced with positive affect. Children know that play is indeed pretend, and therefore is a safe venue in which to express negative thoughts and feelings. Play remains enjoyable even when children are playing

out stories with negative emotions such as fear of monsters, anger at a parent, or fear of losing a parent. A child might play out a story about mother getting very sick with the virus and going to the hospital. The child is preparing themselves for this possibility.

Cognitive Flexibility

In the process of imagining different themes in play, children are developing cognitive flexibility. Feist in 2011 concluded that one feature of creative scientists is cognitive flexibility, that is, the ability to be nimble, break out of old ways of seeing things, and come up with new combinations of ideas. The same is true of creative artists. Boyd (2009) thought that there were similarities between engaging in play and engaging in the arts. He proposed that play contributes to the development of flexibility of cognitive processes in higher mammals and in children. In play, children engage with patterns of information. Art is similar to play in that it also involves cognitive play with patterns of information. In fact, Boyd theorizes that art evolved from animal play. Boyd also thinks that narratives in memory do not need language, but need representations of events. Fein's theory of affective symbolic representations is consistent with this view and brings affective elements into the picture. Pretend play is important because it helps develop these cognitive and affective representations and enables the child to "play" with them and manipulate them into various combinations. This process should help cognitive flexibility develop, which, in turn, enables visualization of many different possibilities in later life.

A recent study by Meyer et al. (2019) found that creative adults were better at imagining distant scenarios than less creative individuals. In addition, creative experts were more likely than other professionals to activate a particular brain area (dorsomedial subsystem) when imagining future situations.

One aspect of cognitive flexibility is the ability to go back and forth between logical thinking and thinking that is more divergent and associative. Vartanian (2019) reviewed the neurological

correlates of creative thinking that support two different thinking processes. Neuroimaging studies have identified the default-mode network as the brain system involved in spontaneous, self-generated thought. This is the type of thought important in open-ended tasks requiring generating a variety of ideas. It is also the neurological network involved in incubation – the process of mind wandering and letting one's thoughts roam. Incubation is an important stage of the creative process where remote associations can occur and lead to creative ideas and solutions to problems. The executive control network is involved in logical thought processes. Vartanian (2019) suggests that neurological findings suggest better ability in creative individuals to switch back and forth between spontaneous thought and evaluative thought processes than less creative individuals. Russ (2020) suggested that pretend play is a venue where children engage in this switching activity and become comfortable with it. In play, there is a free flow of ideation that is then integrated into a narrative. These sequences happen over and over in pretend play. The research support for the association between pretend play and creativity suggests that, because there are so many overlapping processes, similar neurological processes could be involved. This is an important area for future research.

Empirical Support of Associations Between Pretend Play and Creativity

A large number of carefully controlled studies have found an association between pretend play and creativity tasks (See Russ 2014, 2016 for reviews). Pretend play relates to divergent thinking in many studies with preschool and school-age children. In a retrospective study, Root-Bernstein and Root-Bernstein (2006) found that a higher proportion of MacArthur "genius" fellows reported having imaginary worlds in childhood than a control group. Taylor (1999) has found that many creative adults had imaginary friends in childhood.

In the Russ and colleagues research program, we have consistently found significant

associations between imagination and affect expression in play and creativity measures. One advantage of these studies is that the same play task and coding system (Affect in Play Scale; APS, 1993; 2014) were used to measure the play. For children from 6 to 10, puppets and blocks are presented to the child and they are instructed to play anyway they like for 5 min. For children from 4 to 5, a preschool version of the task is used, Affect in Play Scale-Preschool (APS-P), where a variety of toys are presented and the instructions are more structured with initial engagement by the adult evaluator. The play is videotaped and rated by trained coders. The same coding system is used for both the APS and APS-P. A few studies using these play measures are described below. Transforming blocks into objects such as cars or monsters would be coded as imagination. Fantasy themes would also be included in the imagination rating. The coherence of the sequences in the story is reflected in the organization rating. Affective themes such as happy eating, getting hurt, hitting another character, and worrying about monsters would all be coded as affect themes. Enjoyment and engagement in the play would be rated on a comfort scale.

In an early study by Russ and Grossman-McKee (1990), both imagination and quality of the organization of fantasy significantly related to the Alternate Uses Task in 60 first and second grade children. Divergent thinking also was significantly related to frequency of affect in the play narrative and variety of affect categories. These correlations were independent of verbal intelligence. The finding that the relationship was independent of intelligence is important and is consistent with findings in the creativity literature. Other studies with the APS and APS-P with different examiners, different child populations, and in different research labs have found similar results. Both affective process and imagination and organization of the story in play were associated with divergent thinking, independent of intelligence.

Hoffmann and Russ (2012) investigated the relationship between play and storytelling in 61 girls and found that play related to creativity

in storytelling, independent of verbal ability. For the storytelling measure, using the consensus scoring system where stories were evaluated by several raters, imagination in pretend play positively related to creativity in storytelling. Children rated as more imaginative in pretend play were also rated as telling more creative stories. Children who expressed more positive affect during pretend play also tended to tell stories rated as more creative. Also of note, divergent thinking was significantly related to creativity in storytelling. Those children who had higher divergent thinking scores also tended to have higher amounts of affect, larger varieties of affect, and greater amounts of fantasy in the stories they told. These children were also more likely to be rated as having stories that were more likeable, novel, creative, and imaginative. Originality during divergent thinking was also positively related to storytelling affect expression and fantasy, as well as ratings of creativity and novelty. These results suggest a common creative ability across creative tasks, which has implications for the development of creative writing abilities. In a recent study by Fehr and Russ (2016) with preschool children using the APS-P, pretend play was related to divergent thinking and to creativity in storytelling. Divergent thinking and storytelling were also related. Thus, there were similar associations occurred between play, divergent thinking, and storytelling in preschool children and in school-aged children. Through play, it is possible that children develop a mindset for thinking about future possibilities.

Stability of Associations

There have been two longitudinal studies with the APS that have found stability of the associations between pretend play ability and divergent thinking, independent of verbal intelligence. Russ et al. (1999) found that imagination in play of first and second grade children predicted divergent thinking 4 years later. This association continued into high school.

In a second longitudinal study with a different population of girls, early imagination in play

again predicted divergent thinking 4 years later (Wallace and Russ 2015). Positive affect predicted originality. Additional follow-up after 7 years into high school found continued significant associations between imagination in play and divergent thinking.

The importance of the longitudinal results is twofold. First, they suggest that the cognitive and affective processes involved in pretend play and in divergent thinking are trait-like, and stable over time. This ability gives the individual an advantage in successfully engaging in creative activities as an adult. Second, they address the methodological issues raised by Lillard et al. (2013) about play and creativity research. One of their main criticisms of the research in the literature was that the same experimenters carried out the play and creativity tasks. However, in these longitudinal studies, there were different researchers involved and scoring was blind. Even in many of the concurrent studies, there were different researchers and scoring was blind.

Summary

Pretend play experiences provide practice with processes important in creativity. These processes involve imagining different possibilities, forming narratives, generating many ideas, combining and recombining different forms of ideation such as nonverbal images, ideas, affective symbolic representations, memories, and taking on different perspectives. Playing with and expressing these processes contributes to the development of cognitive flexibility, which is crucial for envisioning future possibilities. Scholars of scientific thought and artistic production conclude that cognitive flexibility is important for creative work. Although there are many ways in which children can develop these attributes, pretend play is a natural, built-in, venue that is self-reinforcing and universal. As children develop these abilities, they learn to envision possible future scenarios and accompanying emotions. Further study of the processes in pretend play and how to facilitate development through play is important for future researchers.

Poetry

Mark Freeman

College of the Holy Cross, Worcester, MA, USA

Abstract

Poetry is intimately and necessarily tied to the possible – on at least four, possibly five, levels: the semantic, the referential, the musical, the ontological, and, possibly, the transcendent. Regarding the (possibility of a) fifth level: Sometimes, all of the processes implicated in the four other levels identified come together in such a way as to provide an intimation, or even an experience, of the sacred. Some readers may

be put off by, or even reject, this possibility out of their own naturalistic commitments. This may be especially so for those enmeshed in the discipline of psychology given its avowedly naturalistic commitments and its reluctance to entertain those possibilities that cast these commitments into question. To those adhering to such commitments, it would seem extra important simply to say: It is possible. The method of proceeding in this entry will be to work through the first four levels identified. In doing so, it should become clear that the transcendent level is but a short step from all that has preceded it. Bearing these levels in mind, it should also be clear that the discipline of psychology would benefit greatly by considering the ways in which poetry and poetic processes might inform and shape psychological inquiry.

Poetry and the Possible

There is no need to offer a formal definition of poetry. It would just be one, there are lots of other definitions that might be brought forth, and there is no reason to try to determine which one(s) to privilege. For present purposes, it is more important to identify what poetry generally *does*, what its functions are, and how it enters the world of experience; and what it does, at its core is intimately and necessarily tied to the possible – on at least four, possibly five, levels. The first and most basic level is *semantic*: Poetry employs language, especially metaphorical language, in order to generate new meanings. The second level is *referential*: Poetry can open up and “unconceal” the world, allowing us to see and feel reality in fuller measure. The third level is *musical*: Poetic language is not only about meaning, but sound – the sound of particular words, their rhythm and cadence and melody. The fourth level is

ontological: In opening up and unconcealing the world, it does much the same for us as readers, allowing us to experience our own interiority and depths. As for the fifth – or the possibility of the fifth – it is *transcendent*: Sometimes, all of the processes just enumerated come together in such a way as to provide an intimation, or even an experience, of the sacred. For those readers who may be put off by such talk, opting instead to remain on land (so to speak), all that should be said is: It is possible. Indeed, this *has* been said, most visibly in a chapter titled “The possibility of transcendence” from *The Priority of the Other* (Freeman 2014a). This possibility cannot simply be asserted; reasons need to be provided for why it ought to be entertained. The method of proceeding in this entry will be to work through the first four levels. In doing so, it should become clear that this fifth level, oriented toward the transcendent, is but a short step from all that has preceded it. It should also be clear that the discipline of psychology would benefit greatly by considering the ways in which poetry and poetic processes might inform and shape psychological inquiry.

Also in *The Priority of the Other*, it was suggested that the “default” condition of the human condition – especially that particular form of it that we have come to find in the contemporary world – may be characterized by “ordinary oblivion,” that is, a kind of inattentiveness or “caughtupness” that serves to obscure the world. Arguably, it has always been this way to some degree; we humans are readily lulled into the comfort of familiarity, routine, “common sense,” and sensing. This tendency has been intensified in our time by the great wealth of things that distract us further from beholding what is actually there, before us. Poetry may therefore be more necessary than ever.

Seamus Heaney, in *The Redress of Poetry* (1995), refers to Simone Weil’s extraordinary book *Gravity and Grace* (1997 [1952]), which “is informed by the idea of counterweighting, of balancing out the forces, of redress – tilting the scales of reality toward some transcendent equilibrium.” So too for the activity of poetry:

There is a tendency to place a counter-reality in the scales – a reality which may be only imagined but which nevertheless has weight because it is imagined within the gravitational pull of the actual and can therefore hold its own and balance out against the historical situation. This redressing effect of poetry comes from its being a glimpsed alternative, a revelation of potential that is denied or constantly threatened by circumstances. And sometimes, of course, it happens that such a revelation, once enshrined in the poem, remains as a standard for the poet, so that he or she must submit to the strain of bearing witness in his or her own life to the plane of consciousness established in the poem. (pp. 3-4)

As Heaney goes on to suggest, “As long as the coordinates of the imagined thing correspond to those of the world we live in and endure, poetry is fulfilling its counterweighting function. It becomes another truth to which we can have recourse, before which we can know ourselves in a more fully empowered way” (p. 8).

So far, we have been introduced to the contours of poetry, to the kind of large counterweighting functions it promotes. But how does it actually work? For Heaney, “There is a sensation both of arrival and of prospect, so that one does indeed seem to ‘recover a past’ and ‘prefigure a future’, and thereby to complete the circle of one’s being” (p. 9). How does it do this? And what is its significance for our understanding of the human condition? I now turn to the various levels, or dimensions, of poetry and poetic language in order to begin to address these large questions.

The Semantic: Metaphorical Language and *Poiesis*

In a remarkable chapter titled “The metaphorical process as cognition, imagination, and feeling,” the philosopher Paul Ricoeur is concerned with “metaphor’s claim to yield some true insight about reality” (1978, p. 143), in the context of poetry and beyond. Central to his perspective is the “semantic role of imagination” (p. 145) and the idea that “resemblance,” of the sort frequently associated with metaphor, is a function of “semantic innovation” (p. 146) via the predication of proximity between therefore distant words. “In other words, metaphorical meaning does not

merely consist of a semantic clash but of the new predicative meaning which emerges from the collapse of the literal meaning, that is, from the collapse of the meaning which obtains if we rely only on the common or usual lexical values of our words" (p. 146). What we are thus considering is "the transition from literal incongruence to metaphorical congruence" (p. 147), that "things or ideas which were remote appear now as close. Resemblance ultimately is nothing else than this rapprochement which reveals a generic kinship between heterogeneous ideas" (p. 147).

Ricoeur goes on to draw on Kant's concept of productive imagination by referring to "predicative assimilation," a process that entails "*making* similar, that is, semantically proximate, the terms that the metaphorical utterance brings together" (p. 148). As he explains further,

In order that a metaphor obtains, one must continue to identify the previous incompatibility through the new compatibility. The predicative assimilation involves, in that way, a specific kind of tension which is not so much between a subject and a predicate as between semantic incongruence and congruence. The insight into likeness is the perception of the conflict between the previous incompatibility and the new compatibility. "Remoteness" is preserved within "proximity." To see the like is to see the same in spite of, and through, the different. . . . Imagination, accordingly, is this ability to produce new kinds by assimilation and to produce them not above the differences, as in the concept, but in spite of and through the differences. (p. 148)

Another way to frame the kind of imagination Ricoeur is speaking of here is simply to invoke the idea of *poiesis* – essentially meaning-making. And it is precisely here, in the context of *poiesis*, that we can begin to reflect on the idea of the possible within poetry. For what is being suggested in the account Ricoeur has provided is the idea that, however "solidified" meanings may become, especially through the routines and repetitions of ordinary discourse, language always bears within it a kind of potential, one that can be released and actualized through the semantic role of imagination as it occurs in the creation of metaphor. This process is by no means limited to poetry; as Lakoff and Johnson have argued in their classic text *Metaphors We Live By* (1980), the metaphorical process is part and parcel of the

poetic moment of the human condition itself. In poetry, this process is frequently brought to the fore in such a way as to highlight and intensify our sense of the possible – that is, our sense not only of what language can be but also, and more fundamentally, what *reality* can be.

The Referential: Seeing the World in its Potential

It is but a short step from this first level to the second. "At first glance," Ricoeur (1978) writes, "poetry refers to nothing but itself." The poetic function of language would thus seem to run counter to the referential function of language, which prevails in ordinary, descriptive language. Partially valid though this basic line of thinking may be, Ricoeur seeks to challenge it by highlighting the idea that in poetic language the referential function is not obliterated or suppressed but transformed, such that the sphere of reality being referred to is emergent. As he writes,

Poetic language is no less about reality than any other use of language but refers to it by the means of a complex strategy which implies, as an essential component, a suspension and seemingly an abolition of the ordinary reference attached to descriptive language. This suspension, however, is only the negative condition of a second-order reference, of an indirect reference built on the ruins of the direct reference. This reference is called second-order reference only with respect to the primacy of the reference of ordinary language. For, in another respect, it constitutes the primordial reference to the extent that it suggests, reveals, unconceals – or whatever you say – the deep structures of reality to which we are related as mortals who are born into this world and who dwell in it for a while. (p. 153)

Notice the connection being made here between metaphor and the transformation of reality:

In the same way as the self-abolition of literal sense is the negative condition for the emergence of the metaphorical sense, the suspension of the reference proper to ordinary descriptive language is the negative condition for the emergence of a more radical way of looking at things. (pp. 153–154)

In sum: "In the same way as the metaphorical sense not only abolishes but preserves the literal

sense, the metaphorical reference maintains the ordinary vision in tension with the new one it suggests" (p. 154). It is precisely this tension that yields "a more radical way of looking at things." And it is precisely this more radical way of looking at, and *experiencing*, things that confirm and extend the sense of the possible.

The Musical: Sound, Sonority, and Sensuousness

"It is almost as if we sing to one another all day," Robert Pinsky (1998) has said. In the routine exchanges we have with others, even in the inner dialogues we have with ourselves, there are accents and intonations, inflections, and rhythms. "We do not need to be taught such things," Pinsky adds; "if they were taught in school, we would find them hard and make a mess of them" (p. 3). So it is for "sentence sounds" as well:

Because we have learned to deal with the sound patterns organically, for practical goals, from before we can remember, without reflection or instruction or conscious analysis, we all produce the sounds, and understand them, with great efficiency and subtle nuance. Because of that skill, acquired like the ability to walk and run, we already have finely developed powers that let us appreciate the sound of even an isolated single line of poetry – even if we have very little idea of the meaning. (p. 4)

According to Pinsky, therefore, "The hearing-knowledge we bring to a line of poetry is a knowledge of patterns in speech we have known to hear since we were infants" (p. 6). Along the lines being drawn, poetry is not only a linguistic or semantic art but "a vocal, which is to say a bodily, art. The medium of poetry is a human body: the column of air inside the chest, shaped into signifying sounds in the larynx and the mouth. In this sense, poetry is just as physical and bodily an art as dancing" (p. 8) – and, of course, music. Indeed, there is a fine line, and perhaps at times *no* line, between poetry and music. Consider spoken word poetry, or some forms of hip-hop, or, for that matter, some of Bob Dylan's or Leonard Cohen's songs. The aforementioned semantic dimension remains important in all of these. And this semantic dimension can be intensified, given additional

flesh and form, in and through the music that suffuses it. It's a quite remarkable process: Sometimes, when the lyrics and music line up just right, there can emerge a mysterious sense of concordance, belonging, "fit."

One might ask in this context: At what point does poetry become music? It may seem like a stretch to say so, but I am tempted to say: just about always. I say "just about" mainly because there are some forms of poetry that are highly conceptual, even anti-musical, in a way. But insofar as words are being marshalled not only to *mean* but to *speak*, and to speak in such a way that meter and a kind of proto-melody emerges, musicality is intrinsic to poetic language and, in turn, to the world this language refers to. Indeed, the musicality of poetry deepens and complicates the dimension of referentiality, for if the music may be said to refer, it does so in a much more oblique way than language and thus opens up yet another layer of the possible, one that seeks to articulate and express the sensuous resonances of embodied beings in the world, now being felt anew, thereby disclosing the theretofore concealed depths within us.

The Ontological: Dwelling in the (Infinite) Depths

Yves Bonnefoy (1989), reflecting on the power of poetry, is especially attuned to "the moment when the young reader opens passionately a great book and finds words, of course, but also things and people, and the horizon, and the sky: in short, a whole world given at once to his thirst" (p. 162). For the author of these words, the experience may be more intense still; for, "this world which cuts itself off from the world seems to the person who creates it not only more satisfying than the first but also more real" (p. 164). Bonnefoy goes on to speak of the "impression of a reality at last fully incarnate, which comes to us, paradoxically, through words which have turned away from incarnation" (p. 164). As for the result, it is the opportunity "to bear witness to an existence beyond, to a being, to a plenitude they don't even know how to name" (p. 167). The situation

is a quite remarkable one: words, language, products of discrete cultural worlds, sometimes become imbued with such power and passion as to awaken an “existence beyond,” a magnetic “plenitude” that bears within it intimations of a truly extra-ordinary reality.

One may be reminded here of the wonderful passage from *The Varieties of Religious Experience* (James 1982 [1902]) that articulates the “deeper significance” we sometimes experience with art.

This sense of deeper significance is not confined to rational propositions. Single words, and conjunctions of words, effects of light on land and sea, odors and musical sounds, all bring it when the mind is tuned aright. Most of us can remember the strangely moving power of passages in certain poems read when we were young, irrational doorways as they were through which the mystery of fact, the wildness and the pang of life, stole into our hearts and thrilled them. The words have now perhaps become mere polished surfaces for us; but lyric poetry and music are alive and significant only in proportion as they fetch these vague vistas of a life continuous with our own, beckoning and inviting, yet ever eluding our pursuit. We are alive or dead to the eternal inner message of the arts according as we have lost this mystical susceptibility. (pp. 382–383)

On the basis of what has been said thus far, the “vistas” about which James is speaking here would seem to be not just “continuous” with our own life but a part of it. We may not recognize this; we may be so caught up in the ordinary oblivion of our own being that we lose this “mystical susceptibility” and, in turn, a sense of the depth of our inner life. Poetry can at times revive this susceptibility and reawaken this depth. In doing so, it can serve as an apt reminder that there is “more” to the world, both outer and inner, than meets the eye. Seen from one angle, this “more” – or, as James (1982 [1902]) puts it, “MORE” – signals a “higher part” of our being. But it also signals the sense “*that this higher part is conterminous and continuous with a MORE of the same quality, which is operative in the universe of him, which he can keep in working touch with, and in a fashion get on board with when all his lower being has gone to pieces in the wreck*”

(p. 508). Following James, the MORE “is experienced both *within* and *without*, the ‘higher part’ that is felt to exist within us being, at one and the same time, intimately and necessarily related to what is Other” (Freeman 2014a, p. 202). But that is not all. For even amidst this ostensibly bi-directional energy, there may emerge an intimation of “belonging,” even “a kind of *homecoming*, wherein one’s very belongingness in and to the world is revealed in and through its otherness.” And, “Insofar as the world is revealed as home, as the place where I belong, I am ‘at one’ with it, able, if only momentarily, to move beyond the condition of ordinary oblivion against which the experience is juxtaposed” (p. 171; see also Freeman 2018). This moving beyond may also entail an intimation of the beyond. In doing so, it thus suggests the distinct possibility that this world I inhabit and to which I belong bears within it a still higher sphere of the MORE and a still deeper sense of the possible. How might we understand it? Should we bother?

The Transcendent: The Possibility of Other Worlds

It is not critical that we move any farther in this direction. In experiencing beauty, Elaine Scarry (1999) has noted – including the beauty found in many poems – the object in question not only “fills the mind” but “invites the search for something beyond itself, something larger or something of the same scale with which it needs to be brought into relation.” Phenomenologically speaking, therefore, “beautiful things always carry greetings from other worlds within them.” Nevertheless, whether this “something” she is referring to here truly exists in some immortal, transcendent sphere is, for her, ultimately irrelevant: “Even when the claim on behalf of immortality is gone, many of the same qualities – plenitude, inclusion – are the outcome.” This is by way of saying that, “what happens there is no immortal realm behind the beautiful person or thing is just what happens when there is an immortal realm behind the

person or thing: the perceiver is led to a more capacious regard for the world” (pp. 47–48). Is Scarry right about this? Is the experience of the “immortalist” actually the same as the non-immortalist? Again, should we just “leave well enough alone” and shelve this last (possible) sphere of the poetically possible?

I believe the issue is worth pursuing further, precisely because doing so brings us to another dimension of the possible, one that my own discipline of psychology tends to rule out *a priori* owing to its purely naturalistic account of the human condition. So let us continue. At a most basic level, Jay Parini (2008) has noted, “Words are symbols, and – as such – have resonance beyond their literal meanings. They gesture in directions that cannot be pinned down, and strike chords in the unconscious mind.” And these chords, Parini suggests, contain within them a spiritual dimension. “This all gets very murky,” he acknowledges; “many people do not believe in a world of ‘spirit,’ a word that smacks of dogma to them. . . . Yet poets persist in allowing for a spiritual world, in making associations that one might call ‘religious’ in their poems, linking back to a source of inspiration, to God or whatever (in the words of Paul Tillich) one describes as one’s ultimate concerns.” Once again, it is not necessary to move in this “murky” direction: “one could . . . adequately consider the spiritual dimensions of poetry in psychological terms as well, regarding its project as an attempt to link the conscious mind to deeper, even unconscious, levels of experience” (p. 179). For Parini and many others, though, the conviction that something *more* (MORE) is at work remains, and while their faith commitments may be a part of it, they are not the whole of it. Immanent within the experience itself is an intimation of the transcendent, the sacred, especially the sense that the very givenness of the world bespeaks a gift, resonant with divinity.

Let me fill out this picture a bit more by turning to my friend Bob Cording’s (2019) “explanation” for why he writes and why he links together poetry and theology. I share his words not because he is my friend (for some 35 years), but because he

has taught me a great deal, through his writing and the many exchanges we have had through the years, about the nature of poetry. “I write, first and foremost, to honor the mystery of creation.” More specifically:

I must try to shape a language that will take into account a world we did not make, being faithful to that essential mystery; at the same time, my language must try to faithfully record the terrifying and painful contradictions of human experience; and finally it must do so while remaining open to the intrinsic joy of being. (p. 18)

As Cording goes on to note, in more explicitly theological language,

My task of late has been to evoke what I would call the primordial intuitions of Christianity. . . . that we live in a world we did not create; that God’s immanent presence is capable of breaking in on us at any moment; that most of the time we cannot “taste and see” that presence because we live in a world of self-reflecting mirrors; that by attention alone – “that attention that is so full the ‘I’ disappears,” as Simone Weil says, can we live in the world but outside of our existing conceptions of it. (p. 19)

Some readers are bound to find this statement audacious – first because of Cording’s referring to “God’s immanent presence” and second because he raises the possibility of living in the world “outside our existing conceptions of it.” I don’t know that we need to bring God into the picture – unless by “God” we are simply referring to that intimation of fullness and wholeness that arises within the experience itself. In this context, I follow the lead of the novelist and philosopher Iris Murdoch (1970), who, among others, tries to clear a space for the transcendent without (explicitly) bringing God into the picture. Her reason:

There is . . . something in the serious attempt to look compassionately at human things which automatically suggests that “there is more than this.” The “there is more than this,” if it is not to be corrupted by some sort of quasi-theological finality, must remain a very tiny spark of insight, something with, as it were, a metaphysical position but no metaphysical form. But it seems to me that the spark is real, and that great art is evidence of its reality. (p. 71)

This position may be protested too. Cording, fan of Murdoch though he is, might find her

reluctance to bring God into the picture a problematic gap. He might also suggest that, her own reticence notwithstanding, she is talking about God by any other name. Others may protest for an entirely different reason, and accuse Murdoch of adding in mystical baggage where none is needed. Strictly speaking, they are right: none is needed. But something of the sort she is proposing may still be called for given what art, in this case, poetry, sometimes discloses to us. As George Steiner (1989) adds in this context, one can only offer a “wager” on transcendence, nothing more. That’s okay, though; we are only dealing with the possible here, not the necessary or the inevitable. As for encountering the world apart from our conceptions of it, consider Simone Weil’s (1997 [1952]) fervent wish in this context: “May I disappear in order that those things that I see may become perfect in their beauty from the very fact that they are no longer things that I see.” A qualification: “I do not in the least wish that this created world should fade from my view, but that it should no longer be to me personally that it shows itself.” The ultimate goal: “To see a landscape as it is when I am not there.” On the face of it, this would seem impossible. “When I am in any place, I disturb the silence of heaven and earth by my breathing and the beating of my heart” (p. 37). But might it not be possible, still, to “unself” oneself, as Murdoch (1970) might put it, in such a way as to behold what is truly there? It would be easy enough to simply rule out this possibility. But maybe we shouldn’t. Indeed, might it not be the case that the “tiny spark of insight” about which Murdoch speaks embodies just this going-beyond-conceptions, such that the world bursts forth in its theretofore beclouded radiance? And might it not be the case, in addition, that this radiant bursting-forth, never to end, never to be exhausted, discloses the palpable reality of the infinite – which, ultimately, is nothing other than the living, ever-bountiful reality of possibility itself?

What we are considering here may be seen as a kind of “reenactment” of “the primordial moment of the transcendent.” We could abandon the project of searching for it. But if Cording (2019) is right, we shouldn’t. “If we give up that search we

also give up the world’s fullness” (p. 10) and, with it, our very sense of the possible, given to us along with the bountiful, inexhaustible world.

Summary

Poetry and Psychology: Toward the Psychological Humanities

In view of the five levels of poetry and poetic processes considered herein, poetry ought to receive more attention as an object of psychological inquiry than it generally has. In addition to serving as a significant object of inquiry, however, poetry and poetic processes might also serve as an orienting framework for undertaking psychological inquiry, especially those modes of it that seek to practice fidelity to the complex, often messy, sometimes beautiful stuff that comprises the human condition (Freeman 1993, 1999, 2000). Such inquiry might be thought of as “poetic science” (Freeman 2007, 2011, 2014b). Some of it, however, might also be considered a vehicle inaugurating modes of conceptualizing psychological inquiry that take us beyond science, toward the psychological humanities, and thereby transform the discipline of psychology itself (Freeman 2019, 2020; Sugarman and Martin 2020; Teo 2017).

Political Imagination

Stephen Duncombe¹ and Silas Harrebye²

¹New York University, New York, NY, USA

²Roskilde University, Roskilde, Denmark

Abstract

Political imagination can be defined as a way of transcending political reality, and thus challenging conformity. It can be used to visualize possible futures and to bring to life a real but distant past. It can be a consciously applied strategy or an unconscious way of processing desire. At a time when current politics seems woefully inadequate to face the monumental challenges of bigotry, demagoguery, inequality, climate change, and disease we face today, a revitalization of the political imagination may be necessary, not only to find new solutions but to fundamentally reexplore and reform the frames within which we participate and collaborate in finding these new solutions. Artists, activists, thinkers, and researchers, especially, have a responsibility to use their imagination to not only describe the world as it is and critique its shortcomings but to also conjure up visions of the world as it could be. In sum, *realpolitik* must be joined with a *dreampolitik* of political imagination.

And your young shall see visions, and your old shall dream dreams.

-- Acts 2:17, King James Bible

Introduction: Politics of the Possible and Impossible

Politics is often characterized not by imagination but by pragmatism. “Politics is the art of the possible,” Germany’s nineteenth century “Iron

Chancellor” Otto von Bismarck argued in 1867 while making the case for a practical-minded *realpolitik*. And at the end of the twentieth century, Francis Fukuyama (1992) concluded that we can now no longer imagine a world at the same time different and better than the one ushered in with the end of the Cold War and the victory of liberal democracy. This is an understandable position as those in power have an interest in maintaining the status quo that keeps them in power. As British Prime Minister Margaret Thatcher was fond of saying in response to critics of her neoliberal rule: “There Is No Alternative.”

This lack of imagination infects even well-meaning politicians from relatively well-functioning democracies. The stability which is a trademark for the welfare state also means that creative disruption is typically frowned upon. Recently, a universal basic income and the establishment of a second chamber in Parliament consisting of randomly selected citizens have both been proposed in Denmark. But to many politicians, these proposals are seen as completely “utopian,” that is to say, impossible and therefore ridiculous. Former Danish climate minister Lars Christian Lilleholt characteristically argued against the idea of a permanent citizens assembly (May 2019) simply by pointing to how the *current* system works:

Citizens have every opportunity to influence who runs for Parliament. This is how democracy works in Denmark. To create a citizens assembly which would have a say in climate policies, I have a very hard time imagining.

The minister makes two symptomatic fallacies. Firstly, he argues that because things are as they are, they cannot and should not be any different. This circular reasoning is rooted in classical conservative thinking: what is, and has been, should also always be. Secondly, this is a case of self-confession: Lilleholt has “a very hard time imagining” what is being proposed. That may be the case. But his lack of imagination should not disempower other people’s dreams and initiative. In reality, unfortunately, it often does (Harrebye 2019: 1120–121).

Recently, the global pandemic of Covid-19 has been said to reopen the political space for

philosophers, religious leaders, artists, activists, and others to fundamentally reimagine the values and principles on which to build a new world, exploiting the potential hidden in every crisis. But the politics of imagination is not a recent phenomenon. For as long as there have been those that counsel a sober recognition of the possible, there has been a tradition of envisioning the impossible, and history is full of examples – both inspiring and terrifying – of how the imagination has been used politically.

Definition: What Is Political Imagination?

Politics, as narrowly defined by the Cambridge dictionary, is: “the relationship within a group or organization that allows particular people to have power over others.” (Cambridge, def. 2). So, it can be said that politics constitutes activities involved in getting and using power in public life. *Imagination*, on the other hand, is the “ability to form pictures in your mind,” and the “ability to think of new ideas” (Cambridge, def. 1 and 2). This is the capability of the mind to be creative and resourceful in ways that are neither reliant on the reality one is faced with at present nor limited by personal experience. These new pictures in your mind, or what are commonly called *visions*, can be spatially or temporally distant, improbable, or even impossible. The transforming potential of imagination is that the “move” these visions require and lead to changes in our understanding of the present and how we act within it and towards it. *Political imagination* therefore, at one and the same time, is both political and personal, social and individual. It can be defined as a way of transcending political reality, and thus challenging conformity. It can be used to visualize possible futures and to bring to life a real but distant past. It can be a consciously applied strategy or an unconscious way of processing desire. In a broad sense, political imagination is meant to “designate all those imaginative processes by which collective life is symbolically experienced and this experience mobilised in

view of achieving political aims.” (Glaveanu and Saint Laurent 2015: 559).

By enabling us to project an image of the world, “imagination allows us to perceive certain ends as deserving more or less priority over others and, more particularly, to envisage new ends” (Ferrara 2011, 40). Applied imagination can be seen in business in the entrepreneur who has a bold and daring plan for innovation. Or, in science, with the researcher who dares to follow a hypothesis that may seem ridiculous or fruitless. In politics, it is seen in activists who trust their vision of a world not yet made to guide their actions in the here and now, yet also understand the current context and possesses the skills to make their vision seen by others in the present. The political imaginer is both prophet and evangelist.

History: Utopia as a Model of Political Imagination

Political imagination has a long history. In the West, the *Bible* provided images of mythical lands flowing with milk and honey, and glimpses of a world beyond where the lion lays down with the lamb. Even earlier, Plato laid out his model for an ideal political society in *The Republic*. But perhaps the best-known work of political imagination is *Utopia*, written 500 years ago by Thomas More. Because More’s *Utopia* is an example of political imagination, an instruction guide on how to imagine politically, and literally names the practice, it is worth looking at in some depth.

The imaginary world that More describes is everything his sixteenth century European home was not. The Island of Utopia has a democratically elected government and priesthood, where women can attain positions of power; there is public health and education and Utopians are guaranteed the freedom of speech and religion; Utopia sends foreign aid to the poor of other countries; living and labor are rationally planned for the good of all and, perhaps most utopian of all: there are no lawyers (More was a lawyer himself.) At the root of Utopia, the source from which everything grows, is the shared wealth and

the community of property. The quality of this society is best described thus:

Every house has a door to the street and another to the garden. The doors, which are made with two leaves, open easily and swing shut of their own accord, freely letting anyone in (for there is no private property). (More 1949, 31)

Utopia, however, is more than just a fictive vision of a world turned upside down, and for a book that gives birth to such a commonly used word, *Utopia* is an exceedingly curious text, full of contradictions, riddles, and paradoxes. The grandest – and best known – being the title itself. “Utopia” is a fabricated word, made up by More from the Greek words *ou*, meaning “not,” and *topos*, meaning “place.” Utopia is a place which is, literally, No-Place. Over and over in his book, in all sorts of ways, More creates a vision of an ideal world and then tells us it is not possible. And this paradox is at the heart of More’s understanding of political imagination.

The power of Utopia lies in its ability to be possible and impossible, real and unreal, all at the same time. Through telling the reader a story and leading them on a journey, More convinces them that Utopia is a real place. He gives specific details on how the Utopians live, what their mating customs are, and how their cities are constructed. The world that More sketches is so lucid, so convincing, that the reader imagines they are there. Like watching a good movie or seeing a great performance, they lose themselves into this other world. What is foreign becomes familiar and what is unnatural is naturalized. The reader is not just *told* that an alternative model for structuring society *could* be possible, they are *shown* and thus *feel* that it *is* possible; More is a master of affect. Through his vivid writing, he provides his reader with a vision of another, better world. And then More takes it away by calling the whole thing No-Place.

The problem with most Utopias, be they prophesied by holy men, designed by Vanguard parties, or imposed by political dictators, is that the political imaginaries they propose are presented as The Answer. All the imagining and planning is done by the enlightened few and the job of the rest of the people is to get used to

Political Imagination,

Fig. 1 Map from First Edition of *Utopia*, public domain

it. More solves this problem by refusing us the possibility to believe in *his* Utopia. He takes the reader there – lets them see it and feel it – but then reminds them that this place is just imaginary. But it is too late for one to go home; we have been exposed to the idea of an alternative and our desire to live in such a world has been stoked. We now believe that another world is possible. At this point, we are faced with a choice: we either go home to our world, knowing that something better has been imagined and wallow in despair, or we

imagine a better world ourselves, our own Utopias. *Utopia* is not a rational plan so much as it is a creative prompt: an *imagination machine*. When Fredric Jameson notes that, “utopia emerges at the moment of the suspension of the political” (2004, p. 43), he is stressing how day-to-day politics is a delimiting factor. But when those limits of the political are suspended, as they are through acts of religious, philosophical, and artistic imagination, utopia can become a map for a new political terrain.

Research: The Field of Imagination

Research on political imagination occurs, often in indirect ways, in different scientific domains: in psychology (e.g., Freud 1899; Vygotsky 2004), in anthropology (Riisgaard and Thomassen 2016), in sociology (e.g., Beck 2011; Taylor 2004), in political science (e.g., Browne and Diehl 2019), in philosophy (e.g., Bottici and Challand 2011; Bottici 2019), organizational theory (e.g., Laloux 2014), and in social movement studies (e.g., Duncombe 2007; Haiven and Khasnabish 2014; Solnit 2006). While there are too many research endeavors to do justice to here, several are worthy of special attention.

The conception of imagination that emerges from the German philosopher Hannah Arendt's work on the interrelation between freedom, action, and judgment is one that stresses the capacities for imagination to allow our thinking to "go visiting" outside the political sphere bounded by individuality and experience. As she writes, critical thinking,

goes on in isolation, but by the force of imagination it makes the others present and thus moves in a space that is potentially public, open to all sides; in other words, it adopts the position of Kant's world citizen. To think with an enlarged mentality means that one trains one's imagination to go visiting. (Arendt 1992, 43)

However, imagination needs limits provided by the realities in which one lives. It must be tied to reality, as it is only within this "bounded imagination" that political action is ensured to remain morally grounded (Tyner 2017).

In his book on envisioning real utopias, Erik Olin Wright analyzes cases of institutional innovation that "embody in one way or another emancipatory alternatives to the dominant forms of social organization" (2009, 1). Wright shows how the strategic elements are dependent on historical settings and complex political systems. The best thing we can do, he argues, is to build social empowerment through experimental processes where we "continually test and retest the limits of possibility and try, as best as we can, to create new institutions which expand the limits of themselves" (Wright 2009: 281). In doing so we

not only *envision* utopias – and for Wright they are always plural – but contribute to making them real.

For Benedict Anderson, imagination was essential for the creation of political "realities" like the modern nation state as other, previous, social formations based on religion or kinship crumbled. In his celebrated volume, *Imagined Communities* (1991), Anderson argues that this national imagination is, in part, enabled by forms of mass communication like newspapers and novels, printed in national vernacular languages, which provide a cultural space through which people who may never see or know one another can imagine themselves as having a "national consciousness" and "formed, in their secular particular, visible invisibility, the embryo of the nationally imagined community" (Anderson 1991: 44).

Queer theorist José Muñoz stresses the importance of imagination as a way of creating new possibilities for "minoritarian" people like LGBTQ+ people of color as they renegotiate and reimagine mainstream culture. This "project of world making," as he calls it, "offers a utopian blueprint for a possible future while, at the same time, staging a new political formation in the present." It is often through creative art practices that these worlds are imagined and shared (Muñoz 1999, 200).

Inspiration: Art as Model for Political Imagination

As Anderson and Muñoz remind us, no definition of political imagination is complete without a discussion of the use of art and culture as means of imagining. The poet Audre Lorde writes, "I could name at least ten ideas I would have found intolerable or incomprehensible and frightening, except as they came after dreams and poems." (Lorde 1984, 3). With these words, Lorde imparts two important lessons: The first is that fear is the warden of the imagination. (As the Danish climate minister Lilleholt showed us.) What is unfamiliar, uncommon, or unimaginable is deeply frightening; it upsets our expectations of how the world is

supposed to operate. Lorde's second lesson, however, is equally important: Art can free the imagination from this prison.

It has long been a role of avant garde art to expand the limits of political imagination. The Surrealist André Breton, for example, considered himself a revolutionary: He was a member of the French Communist Party, co-authored a "Manifesto for an Independent Revolutionary Art" with Leon Trotsky, and considered imagination one of the most important tools to bring about revolution. Breton believed that the enemy of imagination is thought. Not thought per se, but conscious thought that has been rationalized and socialized; thought that has been taught to categorize, judge, edit, and correct. As Breton writes in the first *Surrealist Manifesto*:

Under the pretense of civilization and progress, we have managed to banish from the mind everything that might rightly or wrongly be termed superstition, or fancy; forbidden is any kind of search for the truth which is not in conformance with accepted practices. (Breton 1972, 10)

So how to escape the conformity of accepted practices and ideas? For Breton, the path lay through the unconscious. He put great store in dreams as a way of sidestepping around consciousness, and thus providing alternative perspectives and solutions. "Can't the dream also be used in solving the fundamental questions of life?", he asks (Breton 1972: 12). In terms of artistic practice, Breton, as a writer, counseled a technique of automatic writing in which one sits down and writes, fast and furious, before the censors of consciousness can enter (along with the importance of dreams, this method of free association was another of Freud's influences). Surrealist visual artists like Hans Arp, André Masson, and even the non-Surrealist, but deeply mystical, Hilma af Klint practiced "automatic" drawing and painting: Letting their unconscious guide their hand across a canvas. Max Ernst and Salvador Dalí painted imaginary landscapes and objects pulled from their dreams (a practice continued by artists such as the filmmaker David Lynch today). All these art practices were creative efforts to slip by the censors of consciousness and tap into senses and experiences unavailable in the

rational, waking life. As Breton concludes, "Surrealism, such as I conceive of it, asserts our complete nonconformism clearly enough so that there can be no question of translating it, at the trial of the real world, as evidence for the defense" (Breton 1972: 47). Alas, the forces of "the real world" were to also transform Surrealism into a respected art movement and an endless stream of posters, tote bags, and melting clocks sold in museum gift shops.

Other artists of the avant garde were less interested in escaping the strictures of the old "real world" that constrained imagination than they were in using their imagination to create models of a new one. Vladimir Tatlin's *Monument to the Third International* is an instructive example. Tatlin's tower was commissioned soon after the revolution in Russia, in 1919, by The Department of Artistic Work of the People's Commissariat for Enlightenment. The tower was to stand 400 meters tall, almost a quarter higher than the Eiffel Tower, and straddle the Neva river in central Petrograd. Tilting at the same angle as the Earth (23.5 degrees), and taking the idea of "revolution" quite literally, the tower was constructed of three internal revolving levels. At the bottom was a massive glass and steel cube to house the Soviet legislative assemblies, rotating once a year. Above this was a pyramid, where the executive committees would meet, revolving once a month. And over this was a cylinder which held information and propaganda services, that spun once a day. This cylinder was to be faced with a giant screen to show the latest cultural and political news, and equipped with massive loudspeakers to broadcast revolutionary news. At the very top of Tatlin's tower was a hemisphere to house radio equipment, topped by radio towers capable of transmitting world-wide, and a projector with the ability to project propaganda images on the clouds.

Needless to say, Tatlin's Tower was never built. There was not enough steel in all of Russia to construct it, and even if there had been the material to erect it, it is unclear whether it was stable enough to stand. The monument's impracticality was recognized and criticized at the time by Tatlin's cultural and political

Political Imagination,
Fig. 2 Photo of Tatlin's
 Tower, public domain

comrades. Leon Trotsky had this to say, reflecting upon the monument in his book *Literature and Revolution*, “I remember seeing once, when a child, a wooden temple built in a beer bottle. This fired my imagination, but I did not ask myself at that time what it was for...” But now, regarding Tatlin’s monument, he writes: “I cannot refrain from the question: What is it for?” (Trotsky 1957: 247–8). Trotsky, or course, unknowingly answered his own question: What is Tatlin’s monument for? “*To fire the imagination!*” Tatlin himself, as much as he wrapped himself in the utilitarian rhetoric of the revolutionary Russian avant garde, was clear that his design could have another function. The ideal of

“uniting purely artistic forms with purely utilitarian aims,” Tatlin writes in his proclamation *Art into Technology*, is to create “models which stimulate inventions in the business of creating a new world.” (cited in Lodden 1983, 65). It is in this vein that the contemporary Congolese artist Bodys Isek Kingelez, who creates large dream-city installations out of scraps of garbage, says that, “A visionary is someone who dreams of what doesn’t exist yet. He has to make feasible what he has seen.” (Duman 2003).

Avant garde art is not the only cultural arena in which political imagination is expressed. Popular culture – genre literature, songs, movies, TV dramas, video games, social media, and even

advertising – are also platforms for political imagination. One strain of popular culture, science fiction (and fantasy fiction more generally) has been a particularly fruitful field for political imaginings. Arguably the first work of science fiction, Mary Shelley's *Frankenstein*, written in 1818, was a way to imagine a world of technological innovation and question its consequences. Science fiction has attracted political writers such as the socialist H.G. Wells and the libertarian Robert Heinlein and, more recently, popular SF writers such as Ursula Le Guin and Octavia Butler have used the genre as a way to imagine a world outside of patriarchy and white supremacy. These pop culture fantasy imaginings can be dystopian, as is the vision of the mechanized capitalist city in Fritz Lange's 1927 film *Metropolis*, or more recently in the TV series *A Handmaid's Tale* (2017–2018). Or they can be utopian as in the ideal of the Afro-Futurist City-State of Wakanda in the film *Black Panther* (2018). Such fictional imaginings can even lead to real-world actions. For example, fans of the popular Harry Potter series of books and films created an activist group, The Harry Potter Alliance, to take concrete steps to combat gender inequality, climate change, and other issues.

Even sport can be an arena for political imagination. In 2014, Iran played South Korea for a spot in the soccer World Cup. Since women are not allowed to attend games in Iran, two female fans, Fatma Iktasari and Shabnam Kazimi, had to dress up as men in order to get in. Once they were in and the game was underway, they ditched their disguises and made it clear to everyone that real women were joining the happy occasion. The stunt went viral on social media. The intervention not only functioned as a *dilemma action* exposing police powerlessness, it also became a symbol of hope, helping women all around Iran to visibly imagine a world where all citizens, regardless of their gender, could watch a soccer match out in the open (Popovic 2015, 108–110). More generally, sport – like art – is a space of play and playfulness within which to experience and imagine a world operating according to an alternative set of principles.

Critiques: The Dark Side of Political Imagination

Several specters, however, haunt political imagination. Reading what is written above one might well imagine that imagination is almost always on the side of the angels. But probably the most impactful political imagination has been enacted by repressive regimes. Nazism, to take an extreme but influential example, was nothing if not an act of political imagination made manifest. How else to explain the fantasy of a racially homogeneous state and a glorious Third Reich all dressed up with sign, symbol, story, and spectacle? Similarly, the excesses of Stalin's purges and China's Cultural Revolution were equal parts cynical power manipulations and the articulation of an imaginary "pure" politics. Arguably, the most imaginative politics at the moment is that of the far right with their dreams of national greatness, e.g., US President Donald Trump's "Make America Great Again," and nightmares of foreign contagion.

If one problem of political imagination has to do with its effective, repressive implementation, another possible pitfall swings in the opposite direction: That imagination serves as a sort of cultural palliative that retards its political application. Karl Marx located this dilemma in the Utopian visions that reside within religious traditions, describing this "inverted consciousness of the world" as "the sigh of the oppressed creature, the heart of a heartless world, and the soul of soulless conditions. It is the opium of the people." (Marx 1844, np). Stuart Hall and his colleagues at the Centre for Contemporary Cultural Studies took up this critique later, recognizing the positive power of people's ability to create their own resistant (sub)cultures while at the same time identifying the problem of what they called the "magical resolution" of real-world problems through cultural expression (Hall and Jefferson 1993).

It is important to recognize, however, that opium does not just dull pain or put one into a stupor, but can also aid in the dreaming of new realities to be built. Such was the purpose of Dr. Martin Luther King's famous "I Have A Dream" speech delivered in 1963. King begins

his speech with a vivid and chilling account of the nightmare of white supremacy, but then, about half way through, his rhetoric changes as he describes a phantasmagorical dreamworld in which his, and all children, “will not be judged by the color of their skin but by the content of their character.” (King 1963: np). The function of King’s speech was not only to reveal current reality but to imagine the future, inspiring the Civil Rights Movement and giving them a vision to work toward. To paraphrase Jacques Rancière, the revolution starts when the workers stop resting at night to be ready for another day at work, and start dreaming instead (Rancière 1991).

Conclusion: Real and Dreampolitik

At a time when current politics seems woefully inadequate to face the monumental challenges of bigotry, demagoguery, inequality, climate change, and disease we face today, a revitalization of the political imagination may be necessary, not only to find new solutions but to fundamentally re-explore and reform the frames within which we participate and collaborate in finding these new solutions. Artists, activists, thinkers, and researchers, especially, have a responsibility to use their imagination to not only describe the world as it is and critique its shortcomings, but to also conjure up visions of the world as it could be. In sum, the *realpolitik* of Bismark must be joined with a *dreampolitik* of political imagination. This may already be happening. With accelerated communications technology and the social media revolution, political imagination seems to be more fertile and widespread than ever. It is still to be seen, however, whether the overstimulation of information and impressions leads to new and more political imagination or whether there is a saturation point that, if crossed, leads to political apathy and stagnation of imagination or worse: conspiracy thinking, confirmation bias, and delusional politics. For it must also always be remembered that political imagination has led to history’s greatest accomplishments as well as its worst horrors. The qualities and the intentions of our visions matter.

Polyphony

Ingunn Johanne Ness

Faculty of Psychology, Centre for the Science of Learning and Technology (SLATE), University of Bergen, Bergen, Norway

Abstract

The concept of polyphony is often associated with music and refers to multiple independent lines of a melody sounding at once. Further, polyphony is also a concept used by linguistics to describe how different voices and views are simultaneously occurring in a text or in a conversation. Polyphony is an attractive term that has tended to be used in a relatively unobtrusive way explaining a variety of phenomena connected to multiple voices in different contexts. However, one of the most interesting things about the concept of polyphony is that it is so far-reaching: It can be applied to a wide

range of phenomena. This entry defines and explores the concept with a particular emphasis on polyphony and the possible based on a Bakhtinian understanding of the concept, which includes a broadening of one's mind and an exploration of the possible through dialogue, acknowledging each other's different perspectives.

Keywords

Polyphony · Bakhtin · Linguistics · The possible · Dialogism · Experience · Sociocultural psychology

Introduction

While some people think of music when they hear the term polyphony, others think of language and linguistics. The concept of polyphony means literally “many voices” and in music this refers to multiple independent lines of a melody sounding at the same time. However, polyphony is also a concept used by linguistics to describe how different voices and views simultaneously occur in a text or in a conversation.

This entry will start with defining and exploring the concept and then move further into a Bakhtinian notion of polyphony, which includes broadening of one's mind and an exploration of the possible through dialogue, acknowledging each other's different perspectives. Finally, the entry will give an example on how the concept of polyphony was used as an analytical tool in studying interdisciplinary teams (Ness and Dysthe 2020). The team members were engaging in dialogue, broadening their minds, and exploring the possible in the search for developing new ideas and innovation.

Polyphony in Music

In music polyphony is regarded as a multipart musical set technique, where the single voices are equal (Hjorthaug 1999). Polyphonic pieces of music are very horizontal, and the individual voices strive for independence in such a way that

they at the same time tend to have different rhythms and melodic countermovements. In polyphonic music, two or more simultaneous melodic lines are perceived as independent even though they are related. Polyphonic music was a highlight of the Renaissance and Baroque (Kindem 1985), but has also been revived in contemporary music by Bela Bartok and Fartein Valen, among others. An example on a musical form based on polyphony is a “fuge.” In a fuge there will be at least two independent voices and one of the voices will start playing a short theme alone. Then another voice will pick up the same theme while the previous voice plays a contrapuntal accompaniment and the fuge will develop further through how the different voices then pick up on the same theme in different ways. Fuge means “flight.”

Polyphony in Linguistics

Moving on to a different field, linguistics, we find polyphony also to be a much-used term. In linguistics, the belief or idea that a statement has only one sender is strongly opposed. It was with the Russian language philosopher Bakhtin’s literary studies that the unique nature of the speaking subject was seriously questioned. The concept of dialogue and polyphony, which were used by Bakhtin, his followers, and translators, covers the phenomenon on how several voices are expressed in a discourse. However according to Fløttum (1998), polyphony considered as polyphonic is a very vague characteristic, since this will allow at least three interpretations: (1) Polyphony can, firstly, denote that several voices manifest themselves in successive utterances. There is nothing particularly revolutionary about that. (2) Further, we have the second use of polyphony in that special case where you have voice mediality in the speech. It is about repeating and integrating the recipient’s voice into the utterance. This kind of polyphony has further developed the Geneva School and named it diaphony (Roulet et al. 1985). (3) Finally, polyphony can be understood as a manifestation of multiple voices in one and the same utterance. This entry will, in particular, pay attention to the

latter, which is a Bakhtinian understanding of the concept.

Some Central Concepts of Bakhtin: Dialogue, Utterances, Voice and Polyphony, Heteroglossia, and Multivoicedness

When we are looking at polyphony and multiple voices in a Bakhtinian understanding, we also need to include some information on other central concepts in order to contextualize polyphony. Dialogue, utterances, and voice are all notions that Bakhtin wrote about and must be seen in relation to polyphony. In addition, there are two other concepts, very similar to polyphony – those of heteroglossia and multivoicedness.

Starting with dialogue – this comprises both an ontological and an epistemological understanding. Dialogue is, according to Bakhtin, both a fact of life and an ideal to strive for at the same time as it also includes how meaning, knowledge, and creativity are developed in the tension between different voices. Such a notion of dialogue is apt to examine meaning-making processes and the development of new knowledge and understanding that often emerge in the tension between different perspectives (Dysthe 2001; Dysthe and Igland 2001; Morson and Emerson 1990) and was perhaps the most central concept in the works of Bakhtin. When people engage in dialogue, they reveal their voices. The concept of “voice” includes all central aspects of a person and every thought and belief and world view constitutes the person’s voice. “A person enters into dialogue as an integral voice. He participates in it not only with his thoughts but with his fate and with his entire individuality” (Bakhtin 1984, p. 293). Closely connected to voice, is utterance.

An utterance is often seen as the basic notion in Bakhtin’s theories and has several characteristics. According to Hazen (1993), every utterance will be determined by four characteristics: interchange of speaking subjects, consummation (it has to be thematically accomplished through the speakers intention), expressiveness (speaker’s subjective emotional relation toward the object and meaning

of the content of the utterance), and, finally, the utterance has to be addressed to somebody (a particular addressee is being taken into consideration). In this way we can say that utterances are the basic building blocks in a dialogue and what Bakhtin called “the unit for speech communication” (Bakhtin 1986, p. 75). The aim of the dialogue, Bakhtin says, is “to open up and take in the foreign receptionist and try to understand it” (Skorgen 2006, p. 40). In Bakhtin’s view, the utterance will always be expressed from a point of view, a *Weltanschauung*, that doesn’t come out of nothing – it is undetectable from its context of culture (science, arts, politics, etc.) and from the context of a particular individual personal situation. Utterances are embodied acts of voicing our words and the bodily feelings they arouse in others and ourselves (Shotter 2008). What follows in a conversation will consequently be connected to the responsivity of living and growing, embodied beings, responsive both to each other and to the othernesses in their surroundings. This represents a switch from thinking about language in terms of how patterns of already spoken words might be interpreted by us as to their meaning on one hand, to thinking about the spontaneous, bodily effects on us of words in their speaking on the other hand. The polyphonic and thus dialogic utterance is influenced by the expected response and can therefore relate to it in a provocative, stimulating, conveying, distorting, or anticipatory way. Thus, there are no neutral utterances (Bakhtin 1986). Any utterance is always a response to other utterances. The dialogic utterances are always related utterances in the past that can be either confirmed, denied, or avoided at the same time as they are related to what the future can bring from its own based on replies and corresponding utterances.

Utterances exist in every dialogue. As utterances are basic in dialogue, dialogue can be understood as the basic model of language as discursive communication. A sequence of utterances is a dialogue of speaking subjects or voices that respond to former utterances and anticipate the future ones. Put in another way, when people engage in dialogue, we are always responding to

something and we are in constant meaning making.

When it comes to polyphony, Bakhtin never explicitly defines the term but the polyphonic novel is a central theme in *Problems of Dostoevsky’s Poetics*, which is primarily about the author’s position in the text (which will be elaborated later in this entry). Another concept often associated with polyphony, is “heteroglossia” and describes diversity of speech styles in a language. According to Dysthe (forthcoming, 2021) heteroglossia deals with how individual voices are shaped by the languages in different social groups. The term signals that when a person talks, his or her words are expressions of the person’s background, context, personality, view of the world, meanings, and values. The third term, “multivoicedness,” is often easier for most people immediately to relate to since the word itself perhaps is more familiar. Dysthe (forthcoming, 2021) claims that both multivoicedness and polyphony presupposes a dialogic sense of truth with many possibilities – in opposition to a monologic conception of truth, which will have one truth as the only one possible.

Polyphony and the Possible

Based on the previous section, we see how Bakhtin’s perception of utterances and dialogue is closely connected to polyphony. In addition, polyphony has an explicit emphasis on the acknowledgment of different voices. This is helpful in order to avoid a mindset that is monological and dominated by one single perspective. Polyphony literally means “many voiced” and was used to describe literary writing that managed to liberate the voice of characters from the authorial or narratorial voice. Bakhtin’s term is thus normative in the sense that it implies that no authority is dominating and everybody’s voice is equally important. Further, polyphony is always open-ended. This means that it is about seeking surprises and exploring the possible in the sense that no preexisting “scripts” exist. In the following we shall investigate this closer and will start with looking at Bakhtin’s analysis of Dostoevsky’s

Poetics, which revealed an emphasis on the possible through the open-endedness that is characteristic for the notion of polyphony.

Problems of Dostoevsky's Poetics

Bakhtin explored polyphony and dialogue through examining Dostoyevsky's Poetics. He claimed that Dostoyevsky created his novels in full dialogue with the characters and that he listened to the characters' voices.

Bakhtin (1984) suggests that what unfolds in Dostoevsky's novels is a plurality of independent and unmerged voices and consciousnesses, a genuine polyphony of fully valid voices. He thought that Dostoevsky was the first genuine exponent of the fully polyphonic novel since such a novel contained a plurality of unmerged consciousnesses and the character's voice was equally as important as the author's own voice. What unfolds in Dostoevsky's work is not a multitude of characters and fates in a single objective world - but it is rather a plurality of consciousnesses, with equal rights and each with his own world, combined but are not merged in the unity of the event (Bakhtin 1984). The important points here are those indicating that each voice is independent even though they are "combined but not merged" in "the unity of the event" (Shotter 2008).

Bakhtin saw the potential in narratives regarding how to realize polyphony. He meant that in narratives a plurality of independent voices could be realized together with the equally valid voices of the author and other characters. The polyphony that is possible in narratives "is a representation of human languages or voices that are not reduced into, or suppressed by, a single authoritative voice: a representation of the inescapably dialogical quality of human life at its best" (Booth 1984, p. xxii).

It was when analyzing *Problems of Dostoevsky's Poetics*, Bakhtin (1984) referred to polyphony as a new kind of artistic thinking. According to Hazen (1993) this was due to the fact that Dostoevsky went against the traditional narration, which was characterized by privileging harmony and single voicedness. But when reading Dostoevsky, Bakhtin thought that the reader of

Dostoevsky's novels would not have the impression that he or she would be dealing with one single, dominating author, but is instead faced with a multiplicity of authors. This multiplicity creates many possibilities for what is going to happen. Thus it is open-ended. The possible implies that there is no predetermined product or result, instead it is an open process.

In this way we see how polyphony also is closely connected to creativity through the open exploration of possibilities since authors as well as readers meet surprises in the novel. According to Morson and Emerson (1990, pp. 257–267) the characters surprise their creators because a part of creativity in novel writing comes through exposing characters and their ideas to circumstances and situations that will expose them severely (Barnhart 2005). Both discovery and exploration of what is possible becomes a major ingredient of creativity and is connected to using one's imagination. However, being imaginative will always happen in relation to others consciousnesses.

The idea lives not in one person's isolated individual consciousness – if it remains there only, it degenerates and dies. The idea begins to live, that is, to take shape, to develop, to find and renew its verbal expression, to give birth to new ideas, only when it enters into genuine dialogic relationships with other ideas, with the ideas of *others*. Human thought becomes genuine thought, that is, an idea, only under conditions of living contact with another and alien thought, a thought embodied in someone else's voice, that is, in someone else's consciousness expressed in discourse. At this point of contact between voice-consciousness the idea is born and lives. (Bakhtin 1984, pp. 87–88)

In this quote we see how the idea is not within one person's head – instead it is coming to live in between consciousnesses. Bakhtin's view is that in creation of ideas, the dialogical relations are necessary. Different points of view can develop further, and new ones emerge in the meeting between different perspectives. The idea – as Bakhtin also saw in Dostoevsky – is not a subjective, individual, or psychological formation with "permanent resident rights in a person's head; no, the idea is interindividual and intersubjective – the realm of its existence is not individual consciousness but dialogic communion between consciousnesses" (Bakhtin 1984, pp. 87–88).

In an open exploration of the possible, different voices meet – and independent of context, there will be tension between different voices and perspectives. This is why it is necessary that the voices acknowledge this tension and give room for each other (Ness and Dysthe 2020). For Bakhtin, this implies that participants in a dialogue must have an open mind in relation to others. In any imaginative and creative process, dialogical relations are necessary. Different points of view can develop further and new ones emerge in the meeting between different perspectives.

We have so far looked at the concept of polyphony and how to understand it. We will now turn to a more practical aspect and how this concept also can be used as an analytical tool in research investigating creative processes and possibility thinking in interdisciplinary teams.

Polyphony as an Analytical Tool in Studying Interdisciplinary Teams Working with Developing Innovative Ideas

The concept of polyphony has also proven to be relevant as an analytical tool in research on interdisciplinary teams working with developing innovative ideas (Ness 2017). It was constructive in exploring the relational processes in interdisciplinary teams and to understand how the tension between different disciplines and perspectives could be seen as a creative force and result in new knowledge and ideas.

The main research question in the study was: What characterizes creative knowledge processes in interdisciplinary teams working with developing innovative ideas? The study investigated these processes in three interdisciplinary teams consisting of team members from different disciplinary backgrounds. These different backgrounds were ensuring different perspectives and “voices” in the teams. The team members met at the boundaries of their different disciplines to build new ideas and knowledge in collaboration. The idea was that every team member came into the teams with a specific expertise that would not

be accessible to the team otherwise. Then they were supposed to share their individual expertise and knowledge with each other and learn from each other in order for the team as a whole to get a broader common knowledge base that could work as a point of departure for imagining new ideas together in collaboration. True collaboration involved dialogue and to listen to each other and not argue for one’s own views but instead listen and build on each other’s views.

The project went over a period of 2 years and was inspired by ethnography (Geertz 1983). This meant that the researcher spent time in the teams in order to get close to the communication and the interaction in the teams and get a first-hand impression of the processes. Thus, the process of idea development was studied from the beginning to the end, allowing identification of patterns and characteristics across the teams. The fieldwork involved participant observations, focus group interviews, and individual interviews with the team leaders.

Results from the study showed that the team members shared the individual special competencies they brought to the team and learnt from each other (for more see Ness and Riese 2015; Ness and Søreide 2014). The more the different team members learnt from each other, the more innovative ideas they developed. The many perspectives and voices became a polyphony that made them capable of challenging what they knew and in this way the team members could broaden the possible. This kind of possibility thinking was related to the teams’ imagination, and was stimulated by the existence of multiple voices and perspectives within the team.

By confronting and challenging each other, team members seemed to deliberately emphasize the differences, as a means to bring out and combine different perspectives. However, if the perspectives were too far apart and the differences too strong, the team members could not come to an understanding. Then the discussion became unproductive as it failed to generate specific ideas. Each member of the team needed to take into account other’s perspectives, and if this was not possible other team members tried to negotiate

and “translate” the differences to create a shared understanding (Ness and Søreide 2014). Further, to succeed with broadening the team members’ minds and explore different perspectives when they engaged in possibility thinking, it was crucial that the different team members acknowledged each other and didn’t allow any particular voice to become dominant. When the team members met at the boundaries of their disciplines, effective cross-disciplinary collaboration appeared to require that participants could communicate and understand each other and consequently have an open mind. Indeed, according to Bakhtin, the idea begins to live, take shape, to develop, and find its verbal expression only when it enters into genuine dialogic relationships with other ideas. It was clear that when the team members talked with each other and got to know each other, they gradually were making sense of what was said. Such discussions and negotiations involved curiosity toward each other’s viewpoints and acknowledging the differences. If the team members did not acknowledge each other’s knowledge, it would not be a genuine dialogic relationship and then the team might fail to build on the many different perspectives, which also then inhibited the creative processes and exploration of the possible. The polyphony term in a Bakhtinian notion includes this acknowledging aspect – an open dialogue enabled creative processes instead of suppressing it and limiting the chance for innovative ideas to be generated. However, a genuine dialogic relationship is difficult to achieve since often there will be competing voices and people tend to have their own agendas. There can also be a matter of power in the sense that some team members’ opinions can be seen as more “valid” than others – especially if the matter under discussion is closer to some members’ expertise than others. That is why it is so important that teams working with developing innovation are aware of the pitfalls and the importance of activating all voices in order to use the polyphony as a tool to explore the possible.

The findings in the project underscore that team members need to learn from each other and challenge the existing knowledge in the tension between different perspectives in order to be

creative, and the polyphony concept was very constructive in shedding light on this dialogical understanding of knowledge development.

Conclusion and Summary

The concept of polyphony is a notion used in different contexts. Often polyphony is talked about in music, meaning many melodic tones occurring simultaneously and independently. We also find the concept much used in linguistics and how several voices are expressed in a discourse. Polyphony may also designate both the many voices that exist in a group, and the ideal of none being silenced and none allowed to dominate. In this entry we had a particular emphasis on polyphony and the possible with a Bakhtinian approach as the point of departure. In a Bakhtinian view, participants in a dialogue must have an open mind to others as it is in the tension between different voices knowledge and meaning is created. Indeed, in creation of ideas, the dialogical relations are necessary. Different points of view can develop further, and new ones emerge in the meeting between different perspectives. In this way the possible is broadened through developing new ideas. The term polyphony thus served as an analytical tool in a study on how interdisciplinary teams were developing new and innovative knowledge in the tension between different voices. The term polyphony is popular and has been used in a relatively unobtrusive way. This is, however, also one of the most interesting things about the concept: it is rather far-reaching and can be applied to a wide range of phenomena involving diversity and possibility thinking.

Position Exchange Theory

Jack Martin¹ and Alex T. Gillespie²

²Department of Psychological and Behavioural Science, London School of Economics, London, UK

Abstract

Position exchange theory (PET) explains how our life-long immersion within and movement between a wide variety of sociocultural positions contributes to our development as persons with unique capabilities of self- and other understanding, perspective taking, agency, imagination, and creativity. An important part of our sociocultural constitution as persons involves the occupation and taking up of social psychological positions and perspectives within, and extending beyond, the interactive exchanges, routines, practices, and traditions in which we are embedded and which define our ways of life. By using the symbolic resources of language, human beings are able to distance themselves from the here and now and engage in reflection that might involve consideration and perhaps enactment of alternative ways of acting. However, PET stresses the importance of recognizing that even the most sophisticated acts of imagination and creativity have their origins in and are sustained by actual social, physical position exchanges experienced throughout our lives. At the heart of position exchange theory is the fostering of reversibility, whether in children's games like hide-and-seek or in the thrust-and-parry of academic debate. We do not need to imagine ourselves entirely out of our life experiences with others and create possibility de novo. The reversibility that flows from position exchange ensures that our interactivity with others, their actions, lives, and circumstances sets the horizon of our own possibility.

A Brief Introduction to Position Exchange Theory

Human life involves an almost constant exchange of positions. Some of these are solo and physical, such as moving from standing to sitting, exercising to relaxing, waking to sleeping, and vice versa. Others are communal and combine physical and social aspects, such as transitioning between giving and receiving, talking and listening, or performing and watching. Many of these exchanges involve moving and switching between different roles and phases in routine, often reciprocal, sequences of interactivity with others and frequently make use of objects—throwing and catching a ball, hiding and searching behind household features and furnishings in a children's game of hide-and-seek, and sending and receiving emails. Some of these exchanges occur within relatively brief intervals of time, such as stating and listening to opinions voiced in a seminar discussion. Others can stretch over entire lives during which children become adults and novices become experts. So ubiquitous are position exchanges in the personal and communal lives of persons that it is very easy to overlook the profound significance and importance they carry with respect to our life-long development as the kinds of people we become, replete with uniquely human capacities to understand our selves and others, take different perspectives, and exercise agency, imagination, and creativity.

One way of realizing the significance of position exchange for our development as persons living with others is to reflect on how we understand other people and their actions. How, for example, do we anticipate and react to the positions and movements of other drivers when piloting our automobiles? How do we know when and how to take our turns in everyday conversations and activities with others in our

families and circles of friends or coworkers? The general answer that position exchange theory (PET) provides to such questions is that we understand what is happening and what to do in these circumstances because we have previous experiences of being positioned and learning to position ourselves in similar and related situations.

We human beings have developed societies, cultures, and ways of life within which our participation requires us to move across a wide variety of positions in an enormous number of routines and practices in which we engage with other people. Our cultures and societies are replete with conventions, customs, and artifacts that support and assist us to enter into the kinds of positions and changes of position that support our development as intersubjective persons aware of the positions that other people occupy. Perhaps the most important of these are human languages that consist of symbols and semiotic forms that allow human users to distance and separate themselves from their immediate physical and social positions and entertain positions and possibilities removed from situational contexts and constraints. Using language to speak effectively to others requires a speaker to take the perspective of her audience; the speaker attempts to speak on the premise of the listener (Rommetveit 1974). As competent language users, when we think or speak to ourselves, we can do so in ways that move us well beyond our immediate physical and social confines by recalling or linking our thoughts to the words and perspectives of others in different situations or by imaginatively generating possibilities through an ongoing inner conversation.

By participating actively in our communities, societies, and cultures, and availing ourselves of powerful artifacts such as language, we acquire and equip ourselves with the unique social psychological capabilities of persons. A very important part of our sociocultural constitution as persons involves the occupation and taking up of social psychological positions and perspectives within, and extending beyond, the interactive exchanges, routines, practices, and traditions in which we are embedded and which define our ways of life. By using the symbolic resources of

language, human beings are able to distance themselves from the here and now and engage in reflection that might involve consideration and perhaps enactment of alternative ways of acting (Gillespie 2018). However, no matter how abstracted our positions and perspectives become, it is important to recognize that such abstracted forms have their origins in actual social, physical position exchanges experienced earlier in our lives.

Imagination is a powerful, defining capability of personhood, yet it cannot develop apart from concrete experiences of physical-material and social positioning (Zittoun and Gillespie 2016). Even as adults already immersed in vicarious and imaginative forms of perspective taking, it is not easy to alter our customary perspectives and actions. To recognize and alter our habitual ways of interacting with others, it often is necessary to once again experience the physicality and materiality of actual social interactions and exchanges. In particular, many extant programs for broadening and deepening our relations with different others seem to require this kind of social, physical actuality as a basis for advancing our active participation within increasingly diverse and hopefully more inclusive communities (Anner 1995).

Position exchange theory was developed initially by the American philosopher and social psychologist, George Herbert Mead, although Mead himself never used the term. In 2005, Alex Gillespie and Jack Martin published separate articles in the *Journal for the Theory of Social Behaviour* in which they interpreted Mead's earlier writings by placing position and perspective exchange at the center of Mead's social, developmental psychology. Since then, together and separately, Martin and Gillespie (2010, 2013; Gillespie 2012; Gillespie and Martin 2014; Zittoun and Gillespie 2015a) have investigated and theorized in detail the ways in which position exchange enables human beings to develop person-defining capabilities such as perspective taking, agency, creativity, and imagination. The development and exercise of these capabilities, individually and collectively, allow us continuously to envision and enact possibilities that change ourselves, our communities, and the

world. More recently, others have begun to add their own studies and interpretations of position exchange, contributing to an expanding literature that explores further its contribution to human creativity and possibility.

PET, Perspective Taking, and Agency

As biological human beings, persons are born with phylogenetically selected predispositions to orient to the world, especially to other persons, and to remember some of what we experience. These dispositions are present only in the most rudimentary forms at birth and continue to develop throughout individual lives in interaction with the world and others in it (Martin and Gillespie 2010). In early infancy, children experience pre-reflectively. For example, after breastfeeding or observing the movement of a crib mobile, the infant typically is able to reorient to these objects. As growth and experience accumulate, the infant's abilities to orient and reorient to the objects in the world around itself increase dramatically. Cued and assisted by the bodily and facial movements of caregivers, young children follow the gazes of others and begin to use others' reactions as a basis for acting themselves. With frequent and increasing interaction in routine position exchanges with others, children learn to coordinate their participation in simple practices that are repeated over and over again—for example, giving and receiving objects, touching and being touched, observing and performing simple actions, and playing games such as peekaboo and hide-and-seek. As Mead (1934) observed, such routine, coordinated interpersonal exchanges involve taking up related social positions in children's games such as hider and seeker (Gillespie 2006).

These experiences of position exchange enable the young child to recall and anticipate being in one position (e.g., seeker) while occupying the other position (e.g., hider). Each social position sustains a distinct perspective or orientation to act in a particular way. It is the movement between these social positions that enables the child to integrate the two perspectives—anticipating

where the hider might be when in the role of seeker and imagining the other with similar and related anticipations when in the role of hider. A perspective, understood as an orientation and inclination to act, is an experience. One cannot literally take someone else's experience. However, repetitive experiences of position exchange, like that between *hider* and *seeker*, enable children to have experiences that are more or less similar. By imaginatively recalling and anticipating social interactions that they have engaged and experienced, children are able to coordinate in more complex ways with others, to sense and understand others' perspectives as similar to and different from their own, and eventually to require less direct interactional experience to understand more of what is going on around them (Gillespie 2012; Martin and Gillespie 2010; Martin 2012).

When taking the perspective of the other, the child never leaves the domain of her own experience but is able to integrate functionally similar experiences by imaginatively drawing from her personal history of occupying the positions and perspectives she has experienced, which are functionally similar to those of others with whom she has interacted. Understanding integration of perspectives in this way provides a theoretical framework for the emergence of intersubjectivity and the agency it affords. Although actors cannot take each other's perspectives directly, they can quite literally take each other's social positions and thus experience similar perspectives.

With the acquisition of language and the ability to imagine possibilities verbalized, even if not extant in more directly observable ways, the child experiences the social world intersubjectively and interactively (Tomasello 2019). In position exchange it is the movement of actors between social positions which weaves the integration of perspectives that is intersubjectivity. Intersubjectivity seeds agency by enabling children who have been interactive in particular situations to transcend:

their own immediate embeddedness and to either take the perspective of others upon themselves, thus mediating their own activity, or to identify with others and thus act on their behalf ... Although actors gain agency through social interaction, they

subsequently possess agency to the extent that they manage to extricate themselves from those same interactions. (Gillespie 2012, p. 45)

As children are able to coordinate and integrate their positionings (and the perspectives they contain) with those of others, they learn to act toward and understand themselves and others as intentional agents. With age and greater social experience, direct and vicarious, the perspectives and possibilities which children can coordinate, imagine, and employ purposefully to guide their actions increase dramatically and become increasingly abstracted. Children become able to reflect, even to critique, their own points of view and opinions, to theorize about others and their life experiences, and to engage in social comparison and assessment. They are able to imagine how things might be different from what they are and react to these and other imaginings as well as to what actually is present and occurring around them. Eventually, their personal history of social interactivity and the intersubjectivity it bequeaths enable increasingly sophisticated capabilities of imagination and interpretation that allow older children, adolescents, and adults to develop longer-term purposes for themselves and make plans to achieve them. As goal-oriented, imaginative, and reflective agents, they are able to develop their own identities and styles, even as they continue to harvest the social and psychological riches available through their coordinated interactivity and intersubjectivity with others. Through these social interactions and experiences, we emerge through childhood and adolescence as persons with distinctive identities, self-awareness, creative possibility, and rational and moral agency. As person agents we are able to exercise some degree of self-determination, even if we do not always think or choose to do so and even as we continue to be shaped and influenced by the words and actions of others and the world around us.

Position Exchange and Creativity

Persons are uniquely creative beings. We are able to exercise our perspective taking and agentive capabilities in ways that help to determine our

own lives and life projects. Moreover, our interactivity and intersubjectivity with others allow us to coordinate and integrate perspectives and possibilities in the exercise of interpersonal, communal agency. Communal agency is a uniquely human achievement that has rapidly changed us and the world we live in. It gives us the power to create societies, cultures, and ways of life that, in the words of Michael Tomasello (2019) “ratchet up” the means and speed of evolutionary change. Our dynamically interactive and coordinated positioning within our sociocultural contexts has helped to transform our human ontogeny. We are able to operate not only as individual agents but also coordinate our activities with others and act as collective agents. We have developed practices of teaching and learning that are unique to human development. These coordinating practices enable forms “of cooperation with almost total interdependence among individuals” (Tomasello 2019, p. 342). Although many other evolutionary and developmental mechanisms and processes are involved in cooperative human action, position exchange makes important contributions to perspective taking, coordination, and integration as enablers of both our individual and collective agency.

Because the perspective taking and integration that arise from position exchange open up a divergence of possibilities for individual and collective consideration and action, PET is closely linked to human creativity. PET helps to explain how perspective taking develops during human ontogenesis as a consequence of the positions we occupy, take up, and imagine within the physical, material, sociocultural, and psychological space and time of our life experiences and projects. It seems obvious that detailed studies of the life contexts and positioning of creative persons might further our understanding of human creativity.

Life positioning analysis (LPA) is a social psychological and biographical method (Martin 2013, 2016a, 2019) that applies position exchange theory to examine life-long patterns of positioning that typify the lives and life accomplishments of creative people in psychology (Martin 2016b, 2017), athletics (Martin 2013, 2016c), and other walks of life.

LPA (Martin 2013) studies individual lives by examining their interactions and relationships with *particular others* embedded within what Mead (1934) called *generalized others*. Particular others are influential people in the life of a person. Generalized others are salient aspects of the broader social and cultural contexts within which interactions between the person and others occur. LPA consists of an interpretive, recursive examination of importantly influential relationships between particular and general others throughout the life of a person. First, the person’s life narrative is chronologically plotted and searched for patterns of interactivity and position exchange with particular others, especially those that seem to be repeated across different phases of the person’s life. The meaning and significance of these patterns of interactivity then are interpreted through a parsing of the sociocultural conventions, contexts, and traditions within which they occurred. Finally the interactive, interpersonal patterns and themes that emerge are considered in relation to the existential dimensions that run through the person’s life as a whole. Such consideration links patterns and contexts of position exchange and life positioning to the works and projects to which the agentive capabilities and creative urges of the individual have been devoted. These are the activities and creations that have given meaning and significance to the life of the person and stand as the person’s legacy.

Although LPA initially was developed to study individual lives, Martin also has used it to compare and contrast the life positioning and creative projects of pairs of individuals who share related life contexts and interests. Two of these dual biographical studies have examined the lives and works of psychologists: Stanley Milgram’s and Ernest Becker’s lives as related to their very different theories of evil (Martin 2016b) and Carl Rogers’ and B. F. Skinner’s lives as related to their theories of human freedom and control (Martin 2017). In both studies, Martin linked prototypic and often repeated interpersonal interactions and social position exchanges experienced by each of these individuals to the theoretical frameworks and methodological practices they employed in their psychological inquiries and theories.

For example, Rogers' early life interactions within his family displayed a social imbalance that positioned him primarily in the role of listener as opposed to the role of speaker. This imbalance was apparent in his interactions with his parents and older siblings and was sustained by the family's religious convictions that included the ideal "generalized other" of the good, obedient child leading a life of piety that manifests in submission to others and a higher power. This imbalance resulted in a preferred social demeanor in which young Carl kept his feelings to himself and tended to his own upsets and joys while carefully observing and actively listening to others. This characteristic positioning and social posture are readily evident in Rogers' nondirective approach to psychotherapy. However, later in life when he moved to California and became involved in the encounter group movement, he eventually was able to move more easily between positions of active listening to others and genuine expression of his own feelings and experiences. This personal change was intertwined with his mature work in developing person-centered therapy.

In contrast, the position exchange most central to Skinner's personal development and later career was a shift from being controlled by others and his social context to gaining control over his social life by arranging conditions supportive of such a shift. These often involved designing and building devices to aid the desired change. In one such instance, he avoided his mother's disapproval for failing to hang up his pajamas by installing a system of pulleys and written reminders, which was mechanically operated by the opening and closing of his bedroom door. Later in his life and professional career, Skinner was to design several devices and systems, from his laboratory "operant conditioning chambers" to his literary blueprint for a utopian community, to support his experiments and projects.

In such examples, it is possible to glimpse the important roles played by incomplete and reciprocal patterns of position exchange in the lives and creative accomplishments of two of America's most famous psychologists, whose life work also

reflected major themes of freedom and control in American life more generally.

Position Exchange, Imagination, and Possibility

Possibility entails seeing paths of action that, despite starting in the immediate environment, extend far beyond it towards possible futures that are entirely semiotic creations. Instead of being "trapped in the perceptual field" (Köhler 1925), humans live in a temporally and spatially extended environment; the past and possible futures are key aspects of our environment. Possibility lies in the gap between what is immediately perceivable and what is semiotically imaginable as a potential future. But where do these alternative, and semiotically imagined, futures come from? Of course, the future, as it unfolds, will be different from the present, and nobody knows exactly what the future will be, but what is remarkable is the extent to which humans not only can conceive of possible futures but also envision their role in creating them.

Our intersubjective being, built up through experiences of position exchange, creates associations, or mappings, between self and other. And these associations allow possibility to arise through the other. When one sees the fashionable attire of a colleague, this creates the possibility of a more fashionable future self. When one is young and sees the success of those who are older, this can create possible futures for oneself. When one sees the home of a colleague in a foreign country, one can entertain, in imagination, the possibility of relocating. Thus, our possible futures are all around us; they are visible in the actions, achievements, and predicaments of others (Gillespie 2007). But, to unlock these possibilities, to be able to play with them in one's mind, requires an imaginal exchange of position; and imagined positions, we have argued, are grounded in more elementary social, material, and institutional exchanges of position.

To illustrate how geographic re-positioning opens up possibility, consider the analysis of an English woman's diary from World War II

(Gillespie et al. 2007; Zittoun and Gillespie 2015b). The diarist, June, was 18 years old in 1939 and living at home with her sister in rural England. Her diary ends in 1945, shortly after the end of the war. When the government called for women to contribute to the war effort, she displayed the perspective of her community. For example, she describes the women who volunteer for war work as “man-chasing” and “the sort of girl that goes in is what I consider rather brainless.” Already, here, we see possibility being created by a self-other mapping; will she become like them? June chooses to contribute by leaving home and working on a farm producing food for soldiers. In this new community, with access to many enthusiastic male soldiers, her behavior begins to change. By 1942, after multiple dates and love affairs, she decries: “I don’t know what is becoming of me.” She has become “that sort of girl,” and thus there is a clash between her prior views and her current behavior. But the new situation, and her new position as desired, begins to change her perspective: “Oh well, I shan’t be young forever.” This break with her past creates new possibilities for her as the war comes to an end. She could, as her mother expected, return home. Or, she could, as her boyfriend expected, get married and settle down. Or, she could, as she herself desires, live and work as an independent woman enjoying the freedoms of being young. Amid the proliferation of options she writes: “This last month I have not known what to do to decide my future. I am constantly changing my mind.”

What the diary shows is that the geographic and social repositioning of June, out of her home community and into the community of war workers, not only creates new opportunities (e.g., meeting soldiers), but it changes her. First, she gets drawn into a network of boyfriends, then her behavior comes into conflict with the values of her home community, and finally she breaks from those values and chooses to live as a single independent woman. The growth of possibility, revealed in June’s diary, is inextricably bound up with her geographic and social repositioning. Before June psychologically “stepped out” of the perspective of her home community, becoming

committed to alternative life projects, she physically moved out of her home community. This shows the close connection between moving between positions in the social world and moving between perspectives in the psychological domain.

Possibility, from the standpoint of position exchange theory, begins with movement in the geographic and social world. Such movements simultaneously manifest and create possibility. They manifest possibility because they are future-creating. They create possibility because the change entailed, when layered upon previous experiences, opens up a semiotic space for imagining alternatives.

At the heart of position exchange theory is the fostering of reversibility. Things can be like this or that, life can be like it is here or like it is there, and here could become like there. The “I” and the “you” become reversible: seeing the success of the other creates the possibility for self, just like seeing the predicament of the other creates fear for self. For June, initially “that sort of girl” is a possible self. Towards the end of the war, it is the sight of married women who become June’s possible selves. This reversibility, we have argued, has its roots in the elementary reversibility of roles, beginning with physical tactile exchange and working up in complexity, through children alternating roles within games towards adults moving position within more complex institutions. The resultant reversibility means that we do not need to imagine ourselves out of the present and create possibility afresh, *de novo*. Instead, this reversibility means that other people, their actions, lives, and circumstances set the horizon of our own possibility.

Conclusion

Since its first formulations appeared in 2005, position exchange theory has been incorporated into several social psychological theories of perspective taking, agency, and creativity (e.g., Glăveanu 2015, 2018; Hanson 2015; Martin et al. 2010; Wagoner et al. 2015). Experiments (Gillespie and Richardson 2011), field studies (Frank and Ilieva 2015), and applications (Muñoz et al. 2019) have begun to appear that

support its basic tenets. By proposing a viable social psychological mechanism that operates at the level of person-to-person interaction within everyday life experience, position exchange theory contributes to a view of persons as active communal agents within their lives with others. As interactive agents, persons are capable of transcending their immediate circumstances and envisioning novel ways of approaching their individual and collective lives—lives that are fueled by the ever present possibility of transformation through the exercise of uniquely human forms of perspective taking, agency, imagination, and creativity.

- collaborators. Positioning Theory stresses that understanding what people do and what they don't do requires to look at what is permissible to do according to the local moral order that is followed and to the positions that people take in that order. "Positions" are clusters of beliefs that people have with respect to the rights and duties to act in certain ways. "Positioning" refers to the processes of assigning, appropriating, or rejecting positions. Every position both opens and closes possible actions. What people possibly can do is a function of three determinants: the **capacities** of people to do certain things, the **restrictions** imposed upon people to do certain things, and the **intentions** that people have to do certain things. One of the basic functions of society is to both stimulate and contain the possibilities of human agency. The study of the possible thus deals with the understanding of how a category of what might be possible in any given context has the chance of succeeding, yet might be denied due to a range of impermissible positions.

Keywords

Positioning · Capacities · Moral orders · Psychology

This chapter unfolds in three steps. First, the difficulties of psychology to cope with the study of human possibilities will be discussed. Secondly, it will be argued that in order to give possibilities a place in psychology, a triple perspective needs to be adopted: study what people possibly *can do*, what they are *allowed to do*, and what they *actually do*. Thirdly, Positioning Theory will be introduced as a tool to understand how people's space for acting is created.

Positioning Theory

Luk Van Langenhove
Vrije Universiteit Brussels, Brussels, Belgium

Abstract

In general, psychology does not pay a lot of attention to the realm of what people can possibly do as the focus is on explaining what people actually do. A notable exception to this is Positioning Theory, a perspective on psychology developed by Rom Harré and

The Challenges Facing Psychology When Exploring the Possible

People have at every moment of the day the possibility to do different things. When somebody is asked why (s)he is doing something rather than

something else, that person can answer: “I’m doing this because I choose to do so.” This implies invoking **personal agency** that does not need to be accounted for. Another possible answer could be that one did something because someone else asked to do it. Here, an **external factor** is referred to in order to account for the act. A special case is when a person ‘obliges’ him or herself to do a certain thing. In which case the “possible” again refers to personal agency, but now with an accounting that involves an **internal factor** or moral perspective, such as for instance, that with will-power everything is possible, and one can do certain things if one really wants. The three above mentioned accounts of behavior (agency and internal or external justification) illustrate that there is a place for the scientific study of the possible by focusing upon explanations why people may act in certain ways. One would expect that psychology takes this up, but this seems hardly to be the case for reasons related to the foundations of psychological research.

The science of psychology is divided into two different paradigms: one that emphasizes the quest for finding the causes of behavior and another that stresses the understanding of the meaning of behavior. These opposing paradigms come under different names, for instance positivism versus hermeneutics, quantitative or qualitative approaches or objectivism versus subjectivism. They are often related to differences in epistemology and methodology as reflected in the distinction between idiographic and nomothetic research (Van Langenhove 1995). In a groundbreaking book, the *Explanation of Social Behaviour*, Harré and Secord (1974) have labeled these perspectives, respectively, the Old and the New Paradigm. Today, the so-called Old Paradigm is still the mainstream, but the New Paradigm is becoming firmly established too. Below, both paradigms will be briefly presented and their implications for the study of the possible discussed.

Causalities and Predictions: The “Scientism” View

The natural world as we experience it is to a large extent deterministic. This has consequences for

the scientific study of natural phenomena. Take for instance the observation that apples fall from trees. As Newton discovered, this happens as result of gravity and the formula $F = G \frac{m_1 m_2}{r^2}$ applies, where F is the force of attraction between the two bodies, G is the universal gravitational constant, m_1 is the mass of the first object, m_2 is the mass of the second object, and r is the distance between the centers of each object. A similar example is hitting a billiard ball with a cue. As a result, the billiard ball then follows a pre-determined path on the billiard table. The play of forces and the law of inertia allow to predict the exact trajectory that the ball will follow. The same sort of calculations make that it is also perfectly possible to predict where in Brussels on 23 January 2134 at 14.23 GMT, the moon will be visible in the sky. All of this is possible due to a causal link between a chain of events where nothing much is possible except that the Humean¹ laws of causality are followed.

The fact that today the concept of causality is known to humanity, is related to the emergence of the “scientific method” characterized by the use of measurements and of experimental methods where conditions are created to test theories. Obviously, there is an incredible merit in the use of such a “scientific method.” But a problem arises when one assumes that those methods can also be transposed to the study of the social and psychological realm. This assumption is called “scientism” and is a dominant approach on the Old Paradigm (Harré and Secord 1974).

Because of causality, the possibilities of things that can happen remain limited in the natural world, for example, if you are holding an apple and then lose the grip on it, there is only one thing possible: the apple will fall until it reaches another surface. The apple is attracted to the earth as a result of gravity. This causality stands in stark contrast with what happens in the social world, where intentions and agency are crucial to understanding what is going on.

¹It was Hume who first described the nature of such causality.

Meaning and the Discursive Nature of the Social Realm

Indeed, the social world seems to be more open and unpredictable than the natural world. Going back to the example of the position of the moon on that day in the year 2134, there is, for instance, no way to know something about what will happen in the streets of Brussels on that same day. There simply is no causal chain between things that are happening in today's Brussels and what will happen then. The possibilities are much bigger. Although there is no social scientist that will claim to be able to predict what will happen in the year 2134, there is a strong current in social sciences to look for Humean causalities in shorter timespans. Predicting the outcome of the next elections for instance is seen as a doable task for psychologists. Traditionally, the dependent variable will be related to a set of independent variables as any basic textbook will explain. All this is based upon a scientist positivist interpretation of what counts as good research.

But it can be argued that a different approach to the study of the social and the psychological realm is feasible, one that leaves room for a range of possibilities, not only for the causal determinants of what we do. This alternative approach focusses on giving meaning to the world, in particular, the importance of the discursive nature of psychological and social phenomena. For instance, certain pieces of paper are considered to be money that can be used in economic transactions. This is because the Governor of the Central Bank has symbolically put his signature on for instance a twenty Euro note, signifying that that piece of paper has that value and that can be exchanged for goods. There is no causality in this process, only meaning. Children for instance who do not understand the concept of money yet, might happily tear the note to pieces. Behind the reality of money lays the principle of what Searle (2009) called the "declaration". In this example, a piece of paper is regarded to be worth twenty euros if someone with the authority to do so, has declared so. The social world therefore can be regarded as a discursive reality that operates by rules and conventions that are not causally directed.

Bringing the Possible into Psychology

The Old Paradigm in psychology has focused on the behavior of individual people, extending this to people in groups and, subsequently, attempts to establish causal links between behavior and external factors, such as the environment or genetic characteristics. To that has been added cognitive explanations that link behavior to internal cognitive schemes, some of which people are conscious of, others apparently not. Besides these restrictions of positivism, this perspective also implies a lack of the significance of any normative and/or moral conceptions rooted within social realities.

It is to the credit of Harré (2012) to have who pointed out that there is more to psychology than to study behavior and that the discipline might be complemented by on the one hand, the study of the capacities of people to do things and on the other hand, of the restrictions imposed upon them to not to do things (for an overview of the work of Harré, see: Van Langenhove 2011). Following Harré, we can now distinguish between three realms for the development of psychology as a discipline: the study of what people can *possibly* do, what is *permissible* to do, and what people *actually* do. As noted by Harré (2015): "what we can do is broader than what we may or may not do, which is broader than what we actually do." In other words, "may" is a tighter concept than "can" in the realm of human action (Harré 2012, p. 1). Below, the realms of capacities and permissible are discussed from a perspective that embraces the possible.

The Capacities of People to Act

What people actually can do is related to the capacities they have at their disposal. One can, for instance, only play the piano when one has learned to play piano, including reading sheet music and so capacities are related to tasks and tools. Everyday life can be regarded as a continuous series of tasks that need to be fulfilled. Brushing our teeth, sorting out taxes, writing a chapter for a book, painting the house, going jogging, visiting one's parents; they are all based on both practical and cognitive tasks.

Metaphorically, people can be said to have access to a set of tools that they can put to use for performing such tasks. The totality of such tools can be regarded as what people can possibly do.

Mapping the tools people have to perform tasks has to start with bringing in an evolutionary perspective that helps to understand why human behavior is so fundamentally different from animal behavior. That perspective reflects that the evolution of using tools dramatically expanded the range of what is possible. The human species is now capable of (i) using the human body as a tool, (ii) fabricating mechanical tools, and (iii) mobilizing other people as tools. Together this has consequences for how and what to study from a psychological perspective.

As biological beings, people are gifted with different bodily functions that open the way to doing so much more than any other biological creature. The main tools for this are our hands and our brains. The reasons why human beings are doing so well in terms of capacities to act, can to a large extent be related to the Darwinian evolution process that led to the growth of the human brain. But there is more to it: parallel with the development of the brain occurred a loss of specialization of certain parts of the body, notably the hands. On top of it, as the sapiens begun to walk on two legs, the hands became free to be used. First, there is the remarkable result of evolution, that our hands have developed in such a way that they can manipulate material things (tools) in an unprecedented way. This specialization towards unspecialized use of the hand, combined with the plasticity of the brain accounts for the evolutionary adaptation to diverse environments. That same brain also allows the use of language as a communication tool. The resulting development of language led not only in the possibility of sharing ideas with others but also in the development of a further second tool: the imagination of things and the thinking about new possible things.

Second, this human development brought with it the capability to fabricate mechanical external (material) tools. The combined use of the brain and the hands allowed to fabricate tools such as hammers, recipients to store food, weapons, and so on. But the factor that really differentiates the

human species from the animal world is that at the same time, human beings became organized in complex societies where collaboration and division of labor resulted in a dramatic increase of what did and can become possible. In the long process that led to a world full of tools, something important happened; human beings started to collaborate in producing tools and a division of labor emerged. Some people developed skills to produce certain tools which could be traded with other goods. That created a complex social environment that makes that every person in a society can profit from the endeavors and specializations of many other persons. As a result, people live in a sea of possibilities that overpasses their individual capacities.

Third, the common viewpoint on human capacities is that people have remarkable powerful brains that allow language, advanced motor skills, and creative thinking to develop. This is, however, only part of the picture. Perhaps the biggest way to create possibilities is to use the brains of other people. As such, not only are the cognitive capacities of individual people the main reason why we are so good at collaborations (be them forced or on a free basis), but what can be called using the extended brain of other people. So, if we want to fully understand what people do and can do, one has to realize that the capacities of people are not confined to their own brain. The capacity of people is as much the result of their being related to literally thousands of other brains. In other words, the possibilities of people to act depends on many others people.

It may look like a “normal” aspect of modern life, that we can hop on a plane to deliver a lecture at the antipodes and meanwhile prepare the PPT while enjoying a glass of wine and listening to Spotify. But none of this would be possible if we didn’t have a system that makes it possible that somehow thousands of people have spent their time mobilizing their skills to produce all these artifacts. The person on a flight in this example doesn’t need to know how an Airbus 380 is manufactured, nor how to fly it. But (s)he needs to know other things, for instance, how to check in to the relevant airline desk, what to include/not include in their packing, how to navigate

passenger terminals, etc. Most of all, (s)he needs to have trust in others that they will be safe and arrive at their chosen destination using technology developed by unknown others.

The Normative Restrictions to Act Seen from the Positioning Theory Angle

People can achieve a lot because they have the unique power to use tools and mobilize people in an unprecedented way. But it is not because one masters the skills to play a piano, that one can use those skills at any time everywhere. As Harré (2011) puts it: “the scope of what people actually do is very much narrower than what they can do.” This seems to be a neglected aspect of the psychological study of behavior, for sure in the Old Paradigm, but also in a lot of New Paradigm research. One way to overcome this is to examine the beliefs that people have about rights and duties to act in certain ways. Between the domain of what is possible and the domain of what actually happens, lays according to Harré (2011), the domain of the permissible and the impermissible. For Harré, it is in the latter perspective that Positioning Theory has its place, as it tackles the question of what the processes are by which the domain of the permissible is extracted from the domain of the possible.

The origins of Positioning Theory go back to two foundational texts published in the *Journal for the Theory of Social Behaviour* (Davies and Harré 1990; Harré and Van Langenhove 1991) and to an edited volume that appeared in 1999 (Harré and Van Langenhove 1999). Positioning Theory is defined as “an explanatory scheme to understand and study discourse and its relation to different psychic and social phenomena” (Harré and Van Langenhove 1999, p. 2). Furthermore, it is claimed that “a powerful use of positioning theory as an analytical tool is that not only persons and their identities both individual and social, but also societal issues on a cultural level can be tackled with the same conceptual apparatus” (ibid., p. 12). And finally, the authors introduce the following metaphor to explain the power of the theory: if the species-wide and history-long

conversation between people can be regarded as a labyrinth network, then “positioning theory offers a possibility to shift from the perspective of maze traders, those who are within the labyrinth, to a perspective of maze viewers, those who can see the labyrinth form above” (ibid., p. 13). A central aspect of Positioning Theory is that it stresses that understanding what people do and what they don’t do requires to look at what is permissible to do according to the local moral order that is followed and to the positions that people take in that order. Thus “Positions” can be described as clusters of beliefs that people have with respect to the rights and duties to act in certain ways. “Positioning” refers to the processes of assigning, appropriating, or rejecting positions. Every position both opens and closes possible actions.

But positions have to be related to two other perspectives: the storylines that develop within interactions and the speech-acts that are uttered by the persons. Positioning Theory claims that every social situation can be understood by analyzing the mutual determinable triangle of positions, storylines, and speech-acts. What people possibly can do is a function of three determinants: the **capacities** of people to do certain things, the **restrictions** imposed upon people to do certain things, and the **intentions** that people have to do certain things.

At any given moment people live their lives in a multitude of overlapping moral orders. Some of those moral orders are of a very general nature. Others can be very specific and active only in specific spaces and/or for limited timeslots only. In both cases (general or specific), moral orders can be latent or active. Latent moral orders are not “in use” in a certain episode. Van Langenhove (2017) has identified five different types of moral orders: general cultural orders, legal moral orders, institutional moral orders, conversational moral orders, and personal moral orders. Together, the above five varieties of moral orders constitute the invisible moral space in which human agency is deployed.

As noted by the social psychologist Bandura, to be an agent, is to “influence intentionally one’s own functioning and life circumstances” (Bandura 2006, p. 53). This captures well what

agency is. But combining the notion of agency with the above presented analysis allows us to be even more precise about what it is: it is the mobilization of capacities and abilities that one considers to be appropriate to be mobilized for the execution of forethought tasks.

Agency has to be contrasted to non-agency. In the latter, a person is not able to live up to a task. An often-neglected dimension of agency is mental ownership: the actor that sees his/her own mind as independent and acknowledging that (s)he is responsible for their acts. The highest form of creating new possibilities can be found in the realms of free will, that is the shaping of one's destiny by doing things that are permissible in the moral order of the day within its own particular context.

Conclusions

In sum: in order to understand why people are doing certain things out of the possible things they could be doing, one has to take into account:

- The totality of things a person can do in terms of skills and capacities as distributed over a collectivity of persons.
- The capacities of a single person to understand the social situation and deploy the tools and skills necessary to attend to and cope with it.
- The moral and normative aspects of the situation that restrict what is appropriate or permissible to do.

The luxury of possibilities is made possible by two connections between persons: the moral orders and the knowledge fields. The challenge is to understand the dynamics of transforming the possible into realities. What people can possibly do is a space of potentialities defined by the limitations of the personal capabilities and the restrictions imposed by a moral order. The agency of people lays in the possibilities to create new capacities, through training, and inventing, and the possibility to overrule any moral order with a belief that one has to do certain things. The possibilities to act are not limited to individual people. On the one hand,

the capacities to act are related to the mobilization of the extended brain. On the other hand, there are limitations to the possibilities imposed through certain moral orders.

Human beings have a wide range of possibilities to act before them. This should have been a main topic of concern to psychologists right from the emergence of the discipline. But under influence of the scientism model, the study of psychology became narrowed down to what can be observed as behavior. As such, the study of what people are able and allowed to do, almost totally disappeared from the ambitions of psychology. What is perhaps needed is a broader perspective on the actual behavior of people that gives room for possibilities as a subject of study. Positioning Theory can certainly illuminate this by mapping how moral orders operate as fields. In order to approach the issue of possibilities, psychology would do well to redirect its practice away from the positivist perspective. Positioning Theory offers a useful framework in order to understand why people might have at all times a range of possible behaviors before them that will be narrowed down, either substantially to one specific behavior or to a set of possible behaviors from where they can choose to act. This calls for a new type of scientific understanding that combines psychological factors with the sociological. At the end of the day, the challenge for any society is to manage a balance between stimulating and enabling facets of human agency while containing it at the same time.

Department of Psychology and Cognitive
Science, Adam Mickiewicz University in Poznan,
Poznan, Poland

Abstract

Positive psychology is a field of psychology asking about the highest good in life (or “life worth living”) and effective ways of pursuing this good. Positive psychology has been focused on the theory and research on increasing happiness or well-being. Positive psychologists translate this knowledge into clinical and nonclinical

evidence-based practice, for example, in the form of positive psychological interventions. The term positive emphasizes the need to examine positive rather than neutral or negative states in human functioning and experience. The reason for positive focus is that it was a neglected scientific area compared to other fields, for example, psychopathology, a complementary field of relieving suffering or the worst in life. This entry presents positive psychology’s definitions and main contributions to the discipline. Moreover, it presents how positive psychology builds upon classical philosophy and earlier psychology, how it overlaps with similar scientific movements, and its limitations. The final section presents how positive psychology has come to grips with issues many authors thought impossible to address.

Happiness; Well-being; Satisfaction with life; Flourishing; Positive emotions

Definitions

What is the best life possible? What is the highest good in life? When are individuals at their best? How to achieve these global desirable life aims? These are some questions that positive psychology asks. Table 1 presents a considerable variation in how authors have defined positive psychology – “a woolly field with diverse and conflicting views” (Duckworth et al. 2005). This limitation concerning the self-identity of positive psychology was primarily attributed to the youth of the discipline. Nevertheless, after more than two decades, the boundary between what is and is not positive psychology is still considered fuzzy. However, the available definitions of positive psychology bear a clear family resemblance (Fig. 1). Due to its long history and diversity in theoretical

Positive Psychology, Table 1 Positive psychology definitions

Sheldon (2009)	It is a conceptual movement in both the research and applied arms of the psychological community which seeks to rectify the “negative” biases of traditional psychology so that a full accounting of human nature and behavior can emerge.
Sheldon and Ryan (2011)	Understanding what goes right, how adaptive systems function, and why the average person does well, such that most people live lives of integrity and contentment.
The Journal of Positive Psychology	Scientifically informed perspectives on what makes life worth living. It focuses on aspects of the human condition that lead to happiness, fulfillment, and flourishing.
Wikipedia, Community definition	The scientific study of what makes life most worth living, focusing on both individual and societal well-being.

Note. Some authors provided more than one definition as definitions changed depending on context and time

approaches, positive psychology can be considered an integrative “umbrella term” for the theory and research on making life worth living (Park et al. 2004).

First, positive psychology aims to identify and understand the most desirable definite outcomes in life, that is, ultimate goals or life fulfillments worth pursuing for their own sake (e.g., happiness, flourishing, or positive emotions). Second, positive psychology aims to identify and regulate processes (wellsprings) that facilitate these positive outcomes, possibly in the most effective way. Positive psychology usually focuses on positive experiences, positive individual characteristics, and the factors that foster their development.

(healthy mindedness), Gordon Allport (positive human characteristics), Lewis Terman (giftedness and marital happiness), James Watson (effective parenting), Carl Jung (meaning in life), Abraham Maslow and Carl Rogers (humanistic psychology), or Maria Jahoda (ideal mental health) (Gable and Haidt 2005; Seligman and Csikszentmihalyi 2000). Of particular note, around the time Seligman delivered his presidential keynote about positive psychology, Carol Ryff and Burton Singer (1998) promoted the need to study positive human health and flourishing by capitalizing on the philosophical accounts of the good life. Thus, positive psychology at its origins aimed at uniting and invigorating scattered and disparate lines of theory and research to provide a basis for further systematic scientific development (Seligman et al. 2005). Until the foundation of positive psychology, psychological research on positive aspects of life never managed to gain a high enough status to become a prominent field of research and practice.

Positive Psychology as a Scientific Movement

Positive psychology is rooted in dissatisfaction with the state of psychological knowledge at the turn of the twentieth and twenty-first centuries. At that time, psychology focused on the worst in life, for example, human weaknesses, and developed scientifically valid psychological help methods in remedying individual and social problems (Seligman and Csikszentmihalyi 2000). Seligman himself was a recognized author in psychopathology (e.g., learned helplessness). Some authors falsely believe that positive psychology aims to substitute or suppress other areas of psychological research, for example, assuming that what is not positive psychology is considered “negative psychology.” In contrast, most authors emphasize that positive psychology aims to provide new information that complements the psychological account of problematic or sub-optimal human functioning (Gable and Haidt 2005).

Thus, positive psychology might be perceived and defined from a meta-psychological perspective,

that is, as an intellectual force external to the whole body of psychology that aims to reshape psychology (Linley et al. 2006). This involves extending the scope of the investigation, reassigning priorities, restoring the scientific gravity of specific subjects, or introducing more scientific rigor into subjects often examined superficially, speculatively, or taken as granted. The aim was to facilitate evolution towards a more comprehensive discipline of psychology, equally respecting every form of human experience.

A complete science and practice of psychology require an understanding of both suffering and happiness and their interactions, and the development of proven interventions that relieve suffering and enhance happiness. (Seligman et al. 2005, p. 410)

Consequently, positive psychology regarded from this meta-perspective was expected to become redundant once psychology accepts as standard, the study of the positive in life.

My hope is that positive psychology is a movement that will eventually disappear because it becomes part of the very fabric of psychology. [...] There will remain many psychologists who study the problems that afflict us; there will also be a large cadre of psychologists who study the factors that make life more fulfilling, meaningful, and enjoyable. (Diener, 2003, p. 120)

Terminology

Positive Positive psychology dedicated little attention to defining what it means that something is “positive.” Some authors proposed that the primary aim of positive psychology might be to define what is “positive” (Diener 2003). Ed Diener equals “positive” with “good” or “valuable.” For instance, people's choices reflect positive, that is, if individuals consistently choose something, they must consider it positive. Second, people's judgments and experiences reflect positive, that is, something is positive if people are satisfied or pleased with it. Third, value systems based on normative thinking reflect what should be considered positive, for example, positive behavior is based on kindness or gratitude rather than selfishness.

Happiness Primarily, positive psychology used the concept of happiness (and happiness interventions) more often than presently (Seligman et al. 2005). Happiness was mostly abandoned for the sake of other similar concepts, for example, flourishing, thriving, satisfaction, or well-being. This might be partially explained by the fact that happiness is a term that has absorbed ambiguities collected over centuries as it has been extensively used in various contexts for millennia in the everyday language and across different scientific disciplines (Tatarkiewicz 1976). Consequently, happiness might be considered too unwieldy for a scientific term. For instance, some authors in positive psychology use happiness as a synonym for well-being. Some consider happiness as a broader concept than well-being, and some consider happiness as a well-being ingredient.

Character Strengths and Virtues Much positive psychological theory, research, and practice have been dedicated to virtues and character strengths (Peterson and Seligman 2004). Character is the moral aspect of a person leading to actions that improve one's own life and the lives of others. Unlike talent, character strengths depend mainly on motivational factors, that is, in most cases, it is sufficient for a person to endorse a specific intention to succeed in acting on their character strengths (e.g., being kind to others). Positive psychologists developed a list of 24 character strengths reviewing moral traditions in Buddhism, Christianity, Greek philosophy, Hinduism, Islam, Judaism, Confucianism, and Taoism. These strengths were grouped into six overarching virtues: courage, justice, humanity, temperance, wisdom, and spirituality (Peterson and Seligman 2004). Wisdom and knowledge, for example, manifests as creativity, curiosity, open-mindedness, a love of learning, or the ability to take different perspectives. Moderation manifests as forgiveness and mercy, modesty, prudence, careful choice, and self-control. Character strengths and virtues are an essential part of positive psychology because the intentional use of character strengths leads to increased well-being (Koydemir et al. 2021). The work on character strengths presents the most detailed and explicit

account of the eudaimonic perspective within positive psychology.

Clinical Positive Psychology

Despite the main interest in the upper pole of the well-being dimension (e.g., flourishing), positive psychology is also concerned with clinical perspectives (Duckworth et al. 2005). This assumes that even individuals struggling with severe psychological problems are motivated to build their strengths, life satisfaction, and meaning, not just correct their weaknesses. These positive outcomes do not come automatically when suffering is removed. Corey L. M. Keyes' (2005) Complete State Model of Health presents a positive clinical perspective. This model locates individuals across two orthogonal dimensions: presence vs. absence of mental disorders and presence (flourishing) vs. absence (languishing) of well-being. Consequently, some individuals languish despite the absence of mental disorders, and some individuals flourish despite the burden of mental disorders.

Overlap of Positive Psychology with Other Psychological Movements

Hedonic Psychology Several areas of study overlap but do not explicitly integrate with positive psychology. Positive psychology is similar to hedonic psychology (Kahneman et al. 1999). Hedonic psychology is a movement that has received less interest than positive psychology despite some conceptual similarities, for example, hedonic pursuits. Hedonic psychology aims to study "what makes the experience and life pleasant or painful" (Kahneman et al. 1999, p. x). Thus, hedonic psychology covers an aspect of human experience explicitly addressed in positive psychology (Seligman et al. 2005). However, positive psychology set sail to cover a broader range of positive outcomes, focusing on superior performance (the good life) and personal fulfillment (meaningful life). Several key contributors to positive psychology also contributed to hedonic

psychology. For example, Ed Diener, Barbara Fredrickson, and Christopher Peterson.

Health Psychology and Public Health Positive psychology shares concepts with health psychology and public health. This overlap holds if health is considered “complete physical, mental, and social well-being and not merely the absence of disease or infirmity,” as proposed by the World Health Organization (WHO 1946/2006). According to this approach, the study of health must not be reduced to the study of the body. It ought to reach psychological and social aspects. Moreover, health must not be reduced to avoiding adversity. It should be conceptualized positively as reaching the “highest possible level of health” (WHO 2006). The World Health Organization constitution explicitly presents happiness as an overarching value and the ultimate aim for applied science. As with positive psychology, health psychologists seek to develop high-quality interventions that promote health by increasing physical, psychological, and social well-being. Despite its focus on positive aims, positive psychology further increases the overlap with health psychology and clinical psychology by targeting well-being among individuals with severe mental disorders (Geerling et al. 2020) and physical problems (Lai et al. 2019).

Salutogenesis Some positive psychology principles bear a resemblance to the theory of salutogenesis (origins of health) that seeks positive aspects of human experience (Antonovsky 1979). A key concept for salutogenesis is the sense of coherence reflected in understanding and managing the world, maintaining realistic optimism, and leading a meaningful life. As is the case with positive psychology, salutogenesis positions itself as complementary to pathogenesis advocating for the need for psychology to cover the whole spectrum of human functioning along the negative-positive dimension.

Education and School Psychology There are similarities between the fields of interest in positive psychology and education or school psychology (Froh et al. 2011). Education scientists

studied many concepts central to positive psychology over decades, nurturing the best in students and individuals across the lifespan. A bibliographic analysis of the topics addressed by journals devoted to educational psychology revealed that over the past 50 years, the proportion of papers focused on positive psychological concepts has ranged from 25% to 33% (Froh et al. 2011). These contributions covered concepts such as achievements and competencies more often than concepts more central to positive psychology, such as positive emotions, meaning, or satisfaction.

Positive Psychotherapy Despite the similar name, positive psychology and its intervention techniques have little in common with positive psychotherapy developed by Nossrat Peseschkian in 1968 within psychiatry. This is important because positive psychology has also used the term positive psychotherapy to address therapeutic programs for clinical groups based on positive psychological interventions.

Positive Psychology Interventions

Positive psychological interventions are activities that promote positive emotions, beliefs, and behaviors to increase well-being. Multiple interventions offered in various settings have been developed to engage psychological processes such as gratitude or kindness. Several intervention outcomes have been studied, for example, satisfaction with life, positive emotions, engagement, meaning, eudaimonic well-being, or prosocial behaviors. Positive psychology offers validated brief interventions and complex psychological support programs using sequences of positive interventions.

As of 2021, the literature has offered 68 randomized controlled trials of positive psychological interventions with 16,085 participants (Koydemir et al. 2021). The results indicated that positive psychological interventions effectively produced long-term effects of moderate increases in subjective well-being and weak increases in eudaimonic well-being (Koydemir

et al. 2021). Seligman hopes that positive interventions might become positive psychology's most enduring contribution to the development of psychological practice (Seligman et al. 2005).

Positive Psychology Criticism

W.E.I.R.D-Centrism A bibliometric analysis of positive psychological interventions revealed that the majority (78.2%) of intervention research was based on recipients residing in Western countries and represented highly educated individuals with high income (W.E.I.R.D) (Hendriks et al. 2019). Consequently, there is some cultural mismatch in the literature. For instance, positive psychological interventions are less effective for Asians than non-Asians (Ng and Ong 2022). This reflects earlier observations that most psychology authors are affiliated with North American institutions (Thalmayer et al. 2021). Thus, their work is likely to implicitly address a specific worldview that might not recognize the needs of individuals living in other societies and cultures.

Context Positive psychology aims to examine what leads to enhanced well-being. Consequently, some readers might have the impression that the findings presented within the field of positive psychology generalize to all individuals in all circumstances (McNulty and Fincham 2012). However, a more accurate perspective might require an emphasis on contexts by asking under which conditions some traits and processes (e.g., forgiveness or gratitude) serve the well-being and under which conditions they do not influence or undermine well-being (Gruber et al. 2011). This contextual perspective points to the possibility that experiencing and expressing happiness (e.g., positive emotions) does not fit certain situations (e.g., in response to the misery of others). Happiness also can be experienced in a dysfunctional way (as is the case in mania). Finally, happiness can be inherently detrimental to an individual (satisfaction and pride derived despite the absence of sufficient merits) or social (e.g., bragging or presenting hubristic pride that diminishes the self-

worth in others) functioning. This contextual approach insists that psychologists avoid labeling traits, processes, and outcomes uniformly and ultimately positive.

Positive Psychology and the Possible

Is It Possible to Become Happier? Positive psychology as a field of study, to its very beginning, centered on the notion of what is possible and what is impossible within human well-being in general and in becoming happier in particular. Some initial arguments against the aims of positive psychology were that it is not possible to increase happiness intentionally because it is a stable trait. Genetic factors explained this stability (e.g., the high correlation of well-being among monozygotic twins) and general regulatory processes that prevent feeling extraordinary happiness by quickly adapting to favorable circumstances (i.e., hedonic adaptation). The vast literature regarding positive psychological interventions indicated that substantial increases in well-being are possible if individuals engage in intentional activities that promote well-being (Koydemir et al. 2021).

Is Positive Psychology Possible Within Psychology? The development of knowledge about happiness is not always plausible from a historical perspective. Happiness can be perceived "luxury state" that is morally problematic to pursue in the face of misery experienced by most others. Along similar lines, positive psychology might be considered a luxury field of science that deserves less attention, effort, and research resources than perspectives focused on resolving individual and social problems to relieve suffering and despair. Laypeople and decision-makers might expect psychology to explain the causes of phenomena related to violence, suffering, or inequalities before proceeding to the study of happiness. A particular manifestation of such tendencies was the focus of the post-war psychological research on the dark aspects of the human personality that led to mass genocide. Seligman and

Csikszentmihalyi (2000) argued that there were specific periods in history in which society's affluence has provided a foundation for pursuing psychological surplus, for example, developing the human potential to create extraordinarily beautiful (and usually unnecessary) achievements. Over two decades of positive psychology development and its continuous scientific momentum suggest that developing psychology's positive side is possible and feasible.

Summary

Positive psychology is the most recent attempt to revive the question about what is most meaningful in life and how individuals can achieve it effectively. Apart from a basic science perspective, positive psychology is focused on developing and testing interventions to achieve greater well-being. Positive psychology is also criticized for its neglect of non-W.E.I.R.D cultures and an out-of-context one-size-fits-all approach. Among the main achievements of positive psychology is documenting that becoming happier is possible via intentional activity, which can be perceived as a luxury by some individuals and in some social or historical contexts.

Possibility

Ryszard Praszkiere

Institute for Social Studies, Emeritus, University of Warsaw, Warszawa, Poland

Abstract

The aim of this entry was to analyze the way in which people perceive difficult challenges. A specific personality trait is proposed herein, reflecting the way individuals perceive challenges on a “doable” to “not doable” scale, named *possibility* (a blend between “possible” and “creativity”). Possibility is depicted as a cognitive property, balancing the perception of one’s own aptitudes with analysis of the characteristics of a challenge.

The theoretical background of possibility is presented herein, that is, the concept of transgression, Kurt Lewin’s balance of forces, and the majority/minority influence. Moreover, attempts to measure transgression are introduced.

Finally, a method for assessing possibility is presented, that is, a projective questionnaire, characterized by positive psychometric properties validated on a $N_0=1117$ sample.

As *possibility* matters in solving social problems, it is recommended to identify, in future research, methods of training, especially of future leaders and the younger generation, so as to augment their propensity for perceiving challenges as doable.

Possibility · Transgression · Entrepreneurship · Innovations · Challenges · Doability · Self-efficacy

Introducing Possibility

Transgression

Exploring the impossible and overstepping one’s own personal limits have been disputed since the

twentieth century. Erich Fromm (1990) believed that for seeking a higher meaning, individuals try to overstep, as far as possible, the boundaries of chaos. Meanwhile, Abraham Maslow (2019) posited that while meeting one's self-realization needs, an individual may overstep their own psychological limits.

Exploring the impossible is pivotal for many fields, for example, for perceiving the philosophy of history as shaped by a passion for "the impossible" (Derrida 1991, 1995; Mason 2007) and for inventing a new path to the anthropological understanding of "impossible" cultures (Hauser 2009). It is also seen as a value in philosophy (Gutting 2013) and in cognitive sciences (Collins 2000).

Exceeding oneself has long been a focus of transgression studies (Barnhart 1988; Sokal 1996; Madsen 2014). In this vein, Józef Koźielecki coined the term "transgressionism," meaning the psychology of exceeding oneself (Koźielecki 1987, 2001). He identified four basic dimensions of transgressionism, namely, material (toward things), social (toward others), symbolic (toward symbols), and self (toward the self) (Koźielecki 1987; Szewczyk 2014), also mentioning some other dimensions, for example, historical, expansive, and creative (Koźielecki 2001). The focus of this entry is on the self and social spheres.

Disturbing the Balance Between Forces

Following Kurt Lewin's "balance between forces" theory, social and symbolic transgressions breach the status quo and therefore usually meet with resistance, as the system has a tendency to revert to its equilibrium. Lewin claimed that to achieve social change, one needs to destabilize the current equilibrium, establish a new equilibrium, and then stabilize this new equilibrium (Lewin et al. 1939; Lewin 2004). This is applied in practice, for instance, by business or social entrepreneurs, who are inspired to alter a dysfunctional equilibrium (Martin and Osberg 2007; Praszkiar and Nowak 2012).

Majority/Minority Influence

One of the factors protecting the old equilibrium is the majority influence. The famous Asch

experiment documented that even if individuals make obvious wrong choices, most of them tend to conform to the majority's false opinions (Asch 1956; McLeod 2008). A plausible mechanism is that if there are two basic psychological needs, that is, the need to be right and the need to be liked, the latter is often predominant and leads humans to conform to the expectations of others (Deutsch and Gerard 1955).

However, there are individuals who create a minority movement and, through this, influence the majority. They act as agents of social change by questioning established societal perceptions and proposing alternative ideas that challenge existing social norms (De Dreu and De Vries 2001; Gardikiotis 2011; McLeod 2018). In lieu of this, they become "bubbles of new in the sea of old" (Vallacher and Nowak 2007). Such people who act against the prevailing majority opinion and introduce new concepts are sometimes called "positive deviants" (Sternin 2002; Marsh et al. 2004; Elkington and Hartigan 2008).

Origins, Etymology, and Definition

Praszkiar (2019a) presented case studies of such individuals, including the resistance and critique they encountered during the early stage of the launch of their projects: Ricardo Semler, a Brazilian entrepreneur, achieved the "impossible," turning (in the 1970s) a struggling family business into a thriving company with a revenue in excess of \$200 million and creating a partnership-based no-managers management style, now in use across the globe. He faced harsh criticism from his family and the business environment, but clung to his vision of the workplace as a nimble and agile society of co-workers (Praszkiar 2019a, p. 9). Mary Gordon from Canada envisioned a school free from aggression and bullying and achieved this through bringing empathy to classrooms; she did so by inviting neighborhood families with babies for students to learn about and play and sing with. These ideas were initially met with resistance and doubt – a common response to innovation, especially within the school system (Praszkiar 2019a, p.19). Piotr Pawłowski from Poland, who, after an unfortunate dive, broke his spine and remained in a wheelchair with only one

finger moving, launched a national movement for mainstreaming disabled persons, also reshaping the city architecture, as well as computer hard- and software design, to enhance accessibility. In the early stage, skeptics weighed in: “You’re both in wheelchairs; aren’t you biting off more than you can chew?” (Praszkier 2019a, p. 25). Temple Grandin was born autistic and, at that time (mid-1940s), was diagnosed as a severely impaired and hopeless case. Against the opinions of her doctors, family, and friends, Temple Grandin’s mother supported her in pursuing education. She discovered a passion for cattle, and against the advice of experts and friends to postpone her dreams, she became a world-famous university professor and expert in handling cattle (Grandin 2006a), as well as in finding positive ways to turn autism into a benefit (Grandin 2006b).¹

People such as the aforementioned individuals explore the impossible and transgress their mind to the level of previously unthinkable ideas. They perceive as doable intractable challenges that have thus far been seen as unrealizable. Against the pressure of the majority, these individuals seem to have a specific property of the human mind that controls the level of conviction that challenges, even if insurmountable, are achievable (Praszkier 2019a, b).

Along these lines, one may assume that each individual has a tendency to evaluate challenges somewhere on the spectrum between two extremes, namely, “it is obviously undoable” and “it is obviously doable.” This evaluation is a cognitive process, stemming from the balance between perceiving one’s own capabilities and analyzing the features of a challenge.

The proposed name for this mind’s property is *possibility*, which is a blend of “possible” and “creativity” and echoes the pronunciation of “realizability” or “creativity” (Praszkier 2019a, b).

Possibility as an Internal–External Balance

As mentioned before, possibility is a cognitive process, based on balancing the perception of one’s own aptitudes with analysis of the characteristics of a challenge. A higher level of possibility leads to the process of transgression; in Kozielski’s language, transgression relates both to the self and the social environment (“toward others”). It seems important to review the mechanisms contributing to both.

Perception of Own Capabilities (Transgression of Own Self)

The perception of one’s own capabilities may contribute to the level of possibility; some examples are outlined below.

One’s own capabilities may be seen through the lenses of Albert Bandura’s **self-efficacy**, that is, belief in one’s own ability to succeed (Bandura 1977, 1982; Akhtar 2008). High self-efficacy facilitates the execution of sufficient effort, leading to successful outcomes; meanwhile, low self-efficacy is likely to terminate effort early and lead to failure (Stajkovic and Luthans 1998). However, overestimating personal abilities does not lead to better results (Stone 2002).

Julian Rotter’s concept of **locus of control**, that is, the degree to which people believe that they have control over the outcome of the events in their lives, indicates that an internal locus of control leads to the belief that the environment is responsive to one’s own personal actions, while an external locus of control indicates that the environment is seen as uncontrollable (Rotter 1966; Wang and Lv 2017).

Similarly, according to Carol Dweck’s concept, individuals may perceive other people and the world as unchangeable or, on the contrary, as malleable and **changeable** (Chiu et al. 1997; Dweck 2000, 2006). People who do not believe in this malleability typically think that things are set once and for all; research has documented that such people have a much

¹ <https://www.ashoka.org/en-PL/fellow/temple-grandin#intro>; accessed 17 July 2020.

higher tendency to stereotype others (Levy et al. 1998), and they are more inclined to avoid the risk of rejection. Conversely, those who believe in the malleability of the world tend to learn by failure instead of focusing on avoiding rejection (Dweck 2000).

Optimism reflects the extent to which people hold generalized favorable expectancies for their future and anticipate the best possible outcome. Higher levels of optimism have been prospectively related to better subjective well-being in times of adversity or difficulty (Carver et al. 2010). Moreover, optimistic people exert effort, whereas pessimistic people disengage from effort (Carver and Scheier 2014).

Need for Achievement (N-Ach) is an intense and lasting effort to accomplish something difficult, with the determination to win (Murray 1938; McClelland 1961). It may involve setting and accomplishing challenging goals, with a moderate tendency for risk-taking (McClelland 1961; Brockhaus 2017).

These are examples of the personality characteristics that may contribute to building up the perception of one's own capabilities, which is an important element of possibility. However, some other traits may also be considered, for example, **Adversity Quotient** (Stoltz 1999) or **Ambiguity Tolerance** (Budner 1962; Bochner 1965).

Analyzing the Challenge (Transgression toward the Social Environment)

The tendency for risk-taking is related to the external side of possibility's internal–external balance and involves the appraisal of the task and the reconnoitering of Kurt Lewin's "balance between forces" (Lewin et al. 1939; Lewin 2004). It is usually an informed, meticulous process (Bornstein 1998; Drayton 2002, 2005) and, as such, excludes the **Dunning–Kruger Effect**, that is, a bias in which people mistakenly assess their cognitive ability as greater than it is; in particular, people who are ignorant or unskilled in a given domain tend to believe that they are much more competent than they are (Kruger and Dunning 1999).

Evaluating Possibility

Transgression Surveys

Most transgression surveys are constructed in relation to overcoming one's own resentments and opening oneself for forgiveness (e.g., Berry et al. 2001; McCullough et al. 2006; Wong et al. 2013; Sinha and Lu 2016).

Considering transgression as a more general human property (not limited to forgiveness), a transgression questionnaire was built (Ślaski 2010), following Koziński's transgressionism theory. It consists of 61 statements, belonging to Koziński's scales of transgression, for example, creative, material, psychological, familial, social, occupational, and ethical (having high reliability and fairly good validity) (Ślaski 2010).

However, this analytic approach (i.e., through analyzing components) does not capture the final result of possibility's internal–external balance, which relates to the cognitive process preceding the "doable–not doable" conclusion. In light of this, there seems to be a need for a more summarizing measurement.

Measuring Possibility

Along these lines, the Perception of Doability Questionnaire (PoDQ) was constructed (Praszkier and Zabłocka 2021). The underlying concept was to capture the way people evaluate challenges. Diverse challenges were depicted to determine the generalized (i.e., not dependent on a specific situation) way of reacting. In this spirit, the chosen method was a combination of a projective test (being mostly universal) (Piotrowski et al. 1993) and the Psychology of Life Stories approach (McAdams 2001), that is, asking respondents to evaluate the doability of various challenging situations faced by different persons. The assumption was that respondents will identify with the presented persons and will assess their challenges by reflecting their own approach.

At first, 12 short stories were created, reflecting diverse individuals from diverse

regions of the world facing diverse challenges.² Seven competent raters were asked to evaluate these stories for their clarity and difficulty levels; finally, three stories were selected, which received the highest clarity rating and a high (though not very high) difficulty rating (extremely difficult situations would not differentiate the respondents, as such challenges would be seen by everybody equally as obviously undoable).

The selected stories were about one man (from Kenya) and two women (from Nepal and Columbia). The narrative was located in the moment when these heroes were planning a novel and challenging solution to some insurmountable and, thus far, intractable problems. The Likert-scale statements evaluated the doability, for example, “X seems being on a roll and she/he can do it,” “I doubt if X will succeed,” and “It’s too challenging, X will fail.”

The statements were modified in two validation rounds: $N_1 = 220$ and $N_2 = 1117$ (in a Polish population). Finally, eight (out of 12) statements were identified, having a good discrimination power ($M = 0.72$; $Max. = 0.86$; $Min. = 0.45$; $SD = 0.1$) and good reliability (Cronbach’s alpha for all > 0.8).

Summary and Conclusions

This entry constitutes the first step in identifying and understanding the concept of possibility, which is worth further study. Especially important would be to research how possibility relates to other characteristics, for example, empathy, adversity quotient, or creativity (specifically divergent thinking).

Moreover, the PoDQ has thus far only been tested in the Polish culture; it seems important to adapt it also to other cultures.

Finally, as the possibility level matters in solving human problems, it seems valuable to

identify methods of training, especially of future leaders and the younger generation, so as to augment their propensity for perceiving challenges as doable.

Incomplete information · Plausibility · Certainty · Bipolarity · Structure of opposition

Introduction

In common usage, the word “possibility” conveys two main meanings (Hacking 1975). One is physical; then, “possible” means easy to achieve, feasible, as in the sentence “it is possible for Hans to eat six eggs for breakfast.” The other is epistemic; there, “possible” means plausible, as in the sentence “it is possible that it rains to-morrow.”

The formalization of notions of possibility, especially epistemic possibility has a very long history. The modalities *possible* and *necessary* have been present in philosophy at least since the Middle Ages in Europe, based on works by Aristotle and his followers. Thus Theophrastus (c. 371–c. 287 BC) was apparently the first to

develop formal elements of modal logic (Bocheński 1947). Later, works on modalities, in particular temporal ones, have been developed early by Arabic logicians (Rescher 1967). More recently, the modalities *possible* and *necessary* became the building blocks of modal logics that emerged at the beginning of the twentieth century from the works of C. I. Lewis (see Hughes and Cresswell (1968)). In this approach, possibility and necessity are all-or-nothing notions, and handled at the syntactic level, with a semantics for most modal logics in terms of accessibility relations between possible worlds (Gasquet et al. 2014).

This chapter will focus on possibility theory, a setting where possibility and necessity are matters of degree, and which, like probability theory, is based on the notion of set function. It differs from probability theory by the use of a pair of dual set functions (possibility and necessity measures) instead of only one self-dual probability measure (since $Prob(not\ A) = 1 - Prob(A)$, for any event A). Possibility and necessity measures are defined from a possibility distribution which describes a graded plausibility profile over a set of mutually exclusive alternatives. Besides, possibility theory is not additive and makes sense on ordinal structures as well as numerical scales. As we shall see, it is an uncertainty theory devoted to the handling of incomplete information. The qualitative and quantitative versions of possibility theories depart from each other by the way the possibility scale is viewed (as ordinal or numerical), and by the definition of the conditioning operation, respectively, based on minimum operation or on the product.

The name “Theory of Possibility” was coined by Zadeh (1978), who was inspired by a paper by Gaines and Kohout (1975). However, Zadeh was not the first scientist to speak about formalizing notions of possibility. In the following, we first provide a brief overview of proposals made by three forerunners of possibility theory. Then, we present basic ideas and elements of the theory, before exhibiting a structure of opposition involving four set functions at work in possibility theory. Finally we discuss applications of possibility theory, before concluding.

Historical Background

The idea of possibility, as an alternative to probability for modeling uncertainty, was central in the works of one economist, G. L. S. Shackle, and in those of two philosophers, D. Lewis and L. J. Cohen.

G. L. S. Shackle

A graded notion of possibility was introduced as a full-fledged approach to uncertainty and decision in the 1940–1970s by the English economist G. L. S. Shackle (1961), who called *degree of potential surprise* of an event A its degree of impossibility $Imposs(A)$, that is, the degree of necessity Nec of the opposite event, namely $Surprise(A) = Imposs(A) = 1 - Poss(A) = Nec(not A)$.

Shackle's notion of possibility is basically epistemic, it is a "character of the chooser's particular state of knowledge in his present." Impossibility is understood as disbelief. Potential surprise is valued on a disbelief scale, namely a positive interval of the form $[0, r^*]$, where r^* denotes the absolute rejection of the event to which it is assigned. In case everything is possible, all mutually exclusive hypotheses have zero surprise. At least one elementary hypothesis must carry zero potential surprise. The degree of surprise of an event, a set of elementary hypotheses, is the degree of surprise of its least surprising realization. The disbelief notion introduced later by Spohn (1990) employs the same type of convention as potential surprise, but using the set of natural integers as a disbelief scale.

D. Lewis

In his 1973 book (Lewis 1973) the philosopher David Lewis considers a graded notion of possibility in the form of a relation between possible worlds he calls *comparative possibility*. He derives this concept of possibility from a ternary relation of similarity between possible worlds. This nonsymmetric notion of similarity is meant to express statements of the form: *a world j is at least as similar to world i as world k is*. Comparative similarity of j and k with respect to i is interpreted as the comparative possibility of j with respect to k viewed from world i . Such relations are assumed to be complete

pre-orderings and are instrumental in defining the truth conditions of counterfactual statements. Comparative possibility relations $\geq_{II}$ obey the key axiom: for all events A, B, C ,

$$A \geq_{II} B \text{ implies } C \cup A \geq_{II} C \cup B.$$

This axiom was later independently proposed by the first author (Dubois 1986) in an attempt to derive a possibilistic counterpart to comparative probabilities. Such comparative possibility relations are used in the theory of belief revision by Grove (Grove 1988) where they are called systems of spheres, and their dual necessity relation by Gärdenfors (1988) under the name "epistemic entrenchment" (see also (Dubois and Prade 1991)). Besides, the connection between numerical possibility and similarity has been investigated by Sudkamp (2002).

L. J. Cohen

A framework very similar to the one of Shackle was proposed by the philosopher L. J. Cohen (1977) who considered the problem of legal reasoning. He introduced so-called *Baconian probabilities* understood as degrees of provability. The idea is that it is hard to prove someone guilty at the court of law by means of pure statistical arguments. The basic feature of degrees of provability is that a hypothesis and its negation cannot both be provable together to any extent (the contrary being a case for inconsistency). Such degrees of provability coincide with necessity measures.

L. A. Zadeh

Before introducing possibility theory, L. A. Zadeh, originally coming from the fields of electrical engineering and computer sciences, proposed and developed the notion of fuzzy set (1965). In a fuzzy set, elements may have an intermediary degree of membership between complete non membership (0) and complete membership (1), using $[0, 1]$ as a membership scale. Thus, a fuzzy set E on a referential S is defined by a membership function μ_E , and $\mu_E(s) \in [0, 1]$, for $s \in S$, is the degree of membership of s in E . For instance, if E stands for "young," we have $\mu_{young}(20) > \mu_{young}(35)$. Clearly the

definition of μ_E depends on the context: μ_{young} will not be defined in the same way in the context of adult people, or in the more specific context of retired people, or yet in the context of dogs.

Independently from the works of the three previously mentioned authors, Zadeh (1978) proposed an interpretation of membership functions of fuzzy sets as possibility distributions encoding flexible constraints induced by natural language statements. Namely, if all we know about the age of a person, say Peter, is that “Peter is a young adult,” this piece of information will be represented by a possibility distribution such that $Poss(age(Peter) = s) = \mu_{young}(s); \forall s \in S$. Thus, we are uncertain about Peter’s age, and, for example, $s = 35$ will have a degree of possibility of being the value of Peter’s age smaller than $s = 20$.

Moreover Zadeh articulated the relationship between possibility and probability, noticing that what is probable must preliminarily be possible. However, the view of possibility degrees developed in his paper refers to the idea of graded feasibility (degrees of ease, as in the example of “how many eggs can Hans eat for his breakfast”) rather than to the epistemic notion of plausibility laid bare by Shackle, even if in Zadeh’s view, possibility distributions were mainly meant to provide a graded semantics to natural language statements. Nevertheless, the key axiom of “maxitivity” for possibility measures (see below), which fits with the two views, is highlighted by Zadeh (1978).

Basic Elements of Possibility Theory

The basic building blocks of possibility theory were first extensively described in the authors’ books (Dubois and Prade 1980, 1988) and chapters (Dubois and Prade 1998, 2015) (see also (Klir and Folger 1988)). We recall them in this section.

Possibility distribution. Let S be a set of states of affairs (or descriptions thereof), or states for short. A possibility distribution is a mapping π from S to a totally ordered scale L , with top 1 and bottom 0, such as the unit interval $[0, 1]$. The degree $\pi(s)$ estimates to what extent s is

plausibly the actual state. The function π thus represents the state of knowledge of an agent (about the actual state of affairs) distinguishing what is plausible from what is less plausible, what is the normal course of things from what is not, what is surprising from what is expected. It represents a flexible restriction on what is the actual state with the following conventions (similar to probability, but opposite to Shackle’s potential surprise scale):

- $\pi(s) = 0$ means that state s is rejected as impossible.
- $\pi(s) = 1$ means that state s is totally possible (= plausible).

$\pi(s)$ may take intermediary values between 0 and 1; the larger $\pi(s)$, the more possible s is. If S is exhaustive, at least one of the elements of S is a fully plausible actual world, so that $\exists s \in S, \pi(s) = 1$ (normalization). Distinct values may simultaneously have a degree of possibility equal to 1. For instance, if it is known that a numerical quantity lies in an interval $E \subseteq S$, any value in E is totally possible for this quantity and any value outside E is impossible.

Possibility theory is driven by the principle of *minimal specificity*. It states that any hypothesis not known to be impossible cannot be ruled out. More precisely, the possibility degrees should be as high as possible given the available information. A possibility distribution π is said to be at least as specific as another π' if and only if for each state of affairs s : $\pi(s) \leq \pi'(s)$ (Yager (1983)). Then, π is at least as restrictive and informative as π' . Practical methods for constructing possibility distributions are reviewed in (Dubois and Prade 2016).

In the possibilistic framework, extreme forms of partial knowledge can be captured, namely:

- Complete knowledge: for some s_0 , $\pi(s_0) = 1$ and $\pi(s) = 0, \forall s \neq s_0$ (only s_0 is possible); this means that the agent knows or believes that the state of affairs is s_0 .
- Complete ignorance: $\pi(s) = 1; \forall s \in S$ (all states are possible for the agent, because there is no information).

Possibility and necessity functions. Given a simple query of the form “is proposition A true?” where, viewing a proposition as a set of possible states, A is a subset of U , the response to the query can be obtained by computing degrees of possibility and necessity, respectively (if the possibility scale $L = [0, 1]$):

$$\Pi(A) = \sup_{s \in A} \pi(s); \quad N(A) = \inf_{s \notin A} 1 - \pi(s).$$

The value $\Pi(A)$ evaluates to what extent there exists at least one state of affairs in A in agreement with the epistemic state of the agent described by π . It is a measure of consistency of proposition A with the possibility distribution π .

The possibility-necessity duality is expressed by $N(A) = 1 - \Pi(A^c)$, where A^c is the complement of A ; it means that $N(A)$ is all the larger as the opposite event A^c is impossible; $N(A)$ evaluates to what extent all the states of affairs outside A have a low possibility, that is, all the states of affairs with a high possibility are included in A . This leads to interpreting the above expression of $N(A)$ as a degree of certainty of (or belief in) A . Clearly, Π and N increase with set inclusion. Generally, $\Pi(S) = N(S) = 1$ and $\Pi(\emptyset) = N(\emptyset) = 0$.

In the $\{0, 1\}$ -valued case, a Boolean possibility distribution π comes down to the membership function of a classical subset $E \subseteq S$ understood as a set of mutually exclusive possible values for a variable x , and possibility and necessity are then as follows:

- $\Pi(A) = 1$ if $A \cap E$ is not empty, and 0 otherwise: function Π checks whether event A , that is, “ $x \in A$,” is logically *consistent* with the available information “ $x \in E$ ” or not.
- $N(A) = 1$ if $E \subseteq A$, and 0 otherwise: function N checks whether event A (i.e., “ $x \in A$ ”) is logically *entailed* by the available information “ $x \in E$ ” or not (i.e., if A is true in all states of affairs considered possible by the agent).

Possibility measures satisfy a characteristic “*maxitivity*” property $\Pi(A \cup B) = \max(\Pi(A), \Pi(B))$. This expresses that “ A or B ” is possible to the extent that one of A or B is possible. As

opposed to probability, possibility is estimated via the most plausible states in A , neglecting the other states.

Necessity measures satisfy an axiom dual to that of possibility measures, namely $N(A \cap B) = \min(N(A), N(B))$. It means that “ A and B ” is certain to the extent that both A and B are certain. So the necessity function can be viewed as a degree of accepted belief. On infinite spaces, these axioms must hold for infinite families of sets.

A modal logic counterpart of possibility theory, called MEL (Banerjee and Dubois 2014), standing for “Minimal Epistemic Logic”, with a semantics in terms of epistemic states, has been developed for binary possibility and necessity. Possibility and necessity functions Π and N are thus graded counterparts of logical modalities.

Necessity qualification. Human knowledge is often expressed in a declarative way using statements to which a belief/certainty degree is attached. It corresponds to expressing constraints the world is supposed to comply with. Certainty-qualified pieces of uncertain information of the form “ A is certain to degree α ” can then be modeled by the constraint $N(A) \geq \alpha$. The least specific possibility distribution reflecting this information is (Dubois and Prade 1988):

$$\pi_{(A, \alpha)}(s) = \begin{cases} 1 & \text{if } s \in A \\ 1 - \alpha & \text{if } s \notin A. \end{cases} \quad (1)$$

Indeed $N(A) \geq \alpha$ is equivalent to $\Pi(A^c) \leq 1 - \alpha$, which means that states outside A have a possibility degree upper bounded by $1 - \alpha$. Acquiring further pieces of knowledge leads to updating $\pi_{(A, \alpha)}$ into a possibility distribution $\pi < \pi_{(A, \alpha)}$.

A strong possibility function and its dual. Apart from functions Π and N , a measure of *guaranteed possibility* or *sufficiency* can be defined from π (Dubois et al. 2000a): $\Delta(A) = \inf_{s \in A} \pi(s)$. The value $\Delta(A)$ estimates to what extent *all* states in A are actually possible according to evidence. It can be used as a degree of evidential support for all states in A . In contrast, the function Π appears to be a measure of *potential* possibility.

Uncertain statements of the form “ A is possible to degree β ” often mean that all realizations of A are possible to degree (at least) β . They can then be modeled by the constraint $\Delta(A) \geq \beta$. It corresponds to the idea of observed evidence. This type of information is better exploited by assuming an informational principle opposite to the one of minimal specificity, namely, any situation not yet observed is tentatively considered as impossible. This is similar to the closed-world assumption in databases: assuming that what is not reported cannot be true. The most specific distribution, denoted by $\delta_{(A, \beta)}$ in agreement with $\Delta(A) \geq \beta$ is:

$$\delta_{(A, \beta)}(s) = \begin{cases} \beta, & \text{if } s \in A \\ 0 & \text{if } s \notin A. \end{cases}$$

Acquiring further pieces of evidence leads to updating $\delta_{(A, \beta)}$ into some wider distribution $\delta > \delta_{(A, \beta)}$. Such evidential support functions do not behave with the same conventions as standard possibility distributions: $\delta(s) = 1$ means that S is guaranteed to be possible, because of a high evidential support, while $\delta(s) = 0$ only means that S has not been observed yet (hence is of unknown possibility). Distributions δ are generally not normalized to 1, and serve as lower bounds to possibility distributions π representing knowledge (because what is actually observed must not be known to be impossible). The strong possibility function Δ satisfies the characteristic decomposition property $\Delta(A \cup B) = \min(\Delta(A), \Delta(B))$.

Of course, the Δ function possesses a dual function ∇ such that $\nabla(A) = 1 - \Delta(A^c) = \max_{s \notin A} 1 - \pi(s)$. The value $\nabla(A)$ stands as a degree of potential or weak necessity of A , as it is 1 as soon as some state s outside A is impossible. The function ∇ satisfies the characteristic property $\nabla(A \cap B) = \max(\nabla(A), \nabla(B))$. It follows that both functions Δ and ∇ are decreasing with respect to set inclusion. In particular, $\Delta(S) = \nabla(S) = 0$ and $\Delta(\emptyset) = \nabla(\emptyset) = 1$, if $\pi(s) = 0$ for some $s \in S$.

When the possibility distribution δ comes down to the membership function of a classical subset $E \subseteq S$ ($\{0, 1\}$ -valued case), Δ and ∇ become:

- $\Delta(A) = 1$ if $E \supseteq A$ and $\Delta(A) = 0$ otherwise (the direction of inclusion is reversed w.r.t. the necessity function).
- $\nabla(A) = 1$ if $A \cup E \neq S$ and $\nabla(A) = 0$ otherwise.

As highlighted by the complementary nature of conditions $A \cap E \neq \emptyset$, $E \subseteq A$, $E \supseteq A$, and $A \cup E \neq S$ (that insure that the corresponding set functions $\Pi(A)$, $N(A)$, $\Delta(A)$, $\nabla(A)$, respectively, equal 1 in the $\{0, 1\}$ -valued case) altogether provide an encoding of the relative positions of sets A and E . In the graded case, these four set functions induced by the same distribution π are weakly related. Indeed, for all A , the inequality

$$\max(N(A), \Delta(A)) \leq \min(\Pi(A), \nabla(A))$$

holds provided that π and $1 - \pi$ are both normalized. These four set functions can be extended to the case of *fuzzy* events, that is, when A is no longer a classical subset of S , but a fuzzy one (Dubois et al. 2017b), following what was proposed quite early by Zadeh for weak possibility measures (Zadeh 1978).

Representing bipolar information. Handling potential (π) and actual (δ) possibility gives birth to a *bipolar* representation of information (Dubois and Prade 2009). It uses pairs of distributions (δ, π) , where π describes the fuzzy set of values that are not impossible (negative information), while δ describes a fuzzy subset of values that are for sure possible to some extent (positive information). We should have $\forall s; \delta(s) \leq \pi(s)$ for consistency reasons. Possibility theory can thus model bipolar uncertainty, distinguishing between what is actually possible (to some extent) because reported from observations and what is only not ruled out by prior knowledge. Note that possibility distributions induced from certainty-qualified pieces of knowledge combine conjunctively, by discarding possible states, while evidential support distributions induced by possibility-qualified pieces of evidence combine disjunctively, by accumulating possible states.

Besides, this formal setting also makes sense for modeling preferences (Benferhat et al. 2006). Then, the degree $\pi(s)$ estimates to what extent alternative s is not rejected as violating a

constraint, while the degree $\delta(s)$ expresses to what extent s is really satisfactory according to a goal or a desire. The function Δ , thanks to its decomposition property, is instrumental in the modeling of the strength of positive desires (Dubois et al. 2017a).

Conditioning. Notions of conditioning and independence exist for possibility measures. Conditional possibility is defined similarly to probability theory using a Bayesian-like equation of the form (Dubois and Prade 1988)

$$\Pi(B \cap A) = \Pi(B|A) \star \Pi(A)$$

for some suitable operation $\star$. In the numerical setting (when possibility degrees take their values in $[0, 1]$), $\star$ is taken as the product as for probability. However, in the qualitative setting, where one uses a discrete bounded linearly ordered scale, the operation $\star$ cannot be a product and is changed into the minimum.

This remark highlights the two main directions along which possibility theory has been developed: the qualitative and the quantitative settings (Dubois and Prade 1998). Both approaches share the same basic “maxitivity” axiom, but differ when it comes to conditioning, and to independence notions. There are several variants of possibilistic independence (De Cooman 1997; De Campos and Huete 1999; Dubois et al. 1997). Generally, independence in possibility theory is neither symmetric nor insensitive to negation. Even for Boolean variables, independence between events is not equivalent to independence between variables.

Possibility and probability. Possibility theory is a graded theory of uncertainty that somewhat formally parallels probability theory. Possibility theory however departs from the latter by relying on two pairs of dual set functions rather than being based on a unique auto-dual measure. In quantitative possibility theory, possibility and necessity measures can be respectively viewed as upper bounds and lower bound of an ill-known probability (Dubois and Prade 1992). Besides, numerical possibility and necessity measures are special cases of plausibility functions and belief functions respectively, in the sense of Shafer evidence

theory (Shafer 1976, 1987). Lastly, there exist bridges that enable the transformation of probability distributions into possibility distributions, and conversely, under some assumptions (Dubois et al. 1993): from possibility to probability using an extension of Laplace insufficient reason principle; from probability to possibility using dispersion or confidence intervals.

In summary, possibility theory is somewhat similar to probability theory, due to the use of set functions. However, possibility functions are maxitive rather than additive; the dual of a possibility function is another set function expressing degrees of certainty. Incomplete information is more faithfully represented in possibility theory than in probability theory.

The Structure of Opposition Underlying Possibility Theory

The interest for structures of opposition is very old. It dates back to Aristotle time where the square of opposition was built in relation with the discussion of syllogisms. The square of opposition applies both to first order logic and modal logics. We first recall it before presenting the structure of opposition underlying possibility theory. The traditional square of opposition is built with universally and existentially quantified statements in the following way. Consider four statement of the form (A): “all P ’s are Q ’s,” (O): “at least one P is not a Q ,” (E): “no P is a Q ,” and (I): “at least one P is a Q .” They can be displayed on a square whose vertices are traditionally denoted by the letters **A**, **I** (affirmative half) and **E**, **O** (negative half), as pictured in Fig. 1 (where $\bar{Q}$ stands for “not Q ”).

As can be checked, noticeable relations hold in the square provided that there is a non-empty set of P ’s to avoid existential import problems:

- (i) **A** and **O** (resp. **E** and **I**) are the negation of each other.
- (ii) **A** entails **I**, and **E** entails **O** (it is assumed that there is at least one example of P).
- (iii) **A** and **E** cannot be true together.
- (iv) **I** and **O** cannot be false together.

Possibility Theory, Fig. 1 Square of opposition

Another classical example of such a square is obtained with modal logic operators by taking **A** as $\Box p$ (necessarily p), **E** as, $\Box \neg p$ (necessarily “not p ”), **I** as $\Diamond p$ (possibly p), and **O** as $\Diamond \neg p$ (possibly “not p ”), where the duality $\Box p = \neg \Diamond \neg p$ holds.

This structure was almost forgotten with the advent of modern logic after G. Boole. It was rediscovered by Blanché (1966) and then by Béziau (2003), who advocate its interest. Switching to first-order logic notations (e.g., **A** becomes $\forall x, P(x) \rightarrow Q(x)$), and negating the predicates, that is, changing P into $\neg P$, and Q in $\neg Q$ leads to another similar square of opposition **aeoi**, where we also assume that the set of “not- P ’s” is non-empty. Altogether, we obtain eight statements that may be organized in what may be called a *cube of opposition* (Dubois and Prade 2012; Dubois et al. 2020). The front facet and the back facet of the cube are traditional squares of opposition, and the two facets are related by entailments.

Such a structure can be extended to graded notions (Ciucci et al. 2016), using an involutive negation such as $1 - (\cdot)$, and where the mutual exclusiveness of **A** and **E** translates into a sum of degrees less than or equal to 1, while entailments are translated by inequalities between degrees (in agreement with multiple-valued implications defined by residuation). An example of a graded cube is obtained in possibility theory (Dubois et al. 2017b). Indeed, assuming a normalized possibility distribution $\pi: S \rightarrow [0, 1]$, and also assuming that $1 - \pi$ is normalized (i.e., $\exists s \in S; \pi(s) = 0$), we obtain a cube of opposition on Fig. 2, linking $\Pi(A)$, $N(A)$, $\Delta(A)$, $\nabla(A)$, $\Pi(\bar{A})$, $N(\bar{A})$,

Possibility Theory, Fig. 2 Cube of opposition of possibility theory

$\Delta(\bar{A})$, and $\nabla(\bar{A})$. The front and back facets form two squares of opposition, while the side facets express a different property, namely they acknowledge the inequalities $\min(\Pi(A), \nabla(A)) \geq \max(N(A), \Delta(A))$. The thick lines of the top facet means that the sum of the corresponding degrees is less or equal to 1, while the bottom lines of the bottom facet means that the sum of the corresponding degrees is larger or equal to 1. Since these set functions rely on ideas of graded inclusion and degrees of non-empty intersections, the fact that they fit with a graded structure of cube of opposition should not come as a surprise. Thus, the cube in Fig. 2 summarizes the interplay between the different measures in possibility theory.

Applications

Possibility theory has applications in many areas (Dubois and Prade 2015). The main one is the propagation and combination of uncertainty. This takes different forms. In approximate reasoning (Zadeh 1982), possibility distributions representing pieces of information are combined and projected for deriving restrictions on variables of interest. This is also a setting for extending all the results and tools from constraint propagation in Artificial Intelligence (AI), to flexible or prioritized constraints (Dubois et al. 1996). Possibility theory has been applied early to computation with

fuzzy intervals (Dubois et al. 2000b): Given two ill-known quantities x and y represented by possibility distributions on the real line, one computes the possibility distribution restricting the possible values of $f(x, y)$ where f is some function.

Possibilistic logic (Dubois et al. 1994; Dubois and Prade 2014, 2018, 2019) extends classical logic with certainty levels modeled by lower bounds of necessity measures, and has a semantics in terms of possibility distributions over sets of interpretations. Generalized possibilistic logic (Dubois et al. 2017c), a weighted extension of MEL (Banerjee and Dubois 2014), handles both necessity and possibility as graded modalities. This logic has found various applications to many AI problems, in relation with the representation of epistemic states and their handling when reasoning from and about them. The qualitative possibilistic setting also applies to *exception-tolerant reasoning* by providing a simple method for making assumptions about the normal course of things, inferring provisional plausible conclusions, and revising these conclusions when new information comes in (non-monotonic reasoning) (Benferhat et al. 1998). Possibility theory also applies to *information fusion* (Benferhat et al. 2002b; Dubois et al. 1999). Besides, possibilistic logic has graphical counterparts under the form of possibilistic Bayesian-like nets (Benferhat et al. 2002a) which may have a qualitative or a quantitative flavor depending on the type of conditioning which is used.

Possibility theory also has applications in information systems. It uses a *fuzzy pattern matching* mechanism where patterns express flexible requirements modeled by means of fuzzy sets, and data (describing items) pervaded with imprecision and uncertainty are represented by means of possibility distributions (Dubois et al. 1988). The querying (Pivert and Prade 2015) and the design (Link and Prade 2019) of databases pervaded by uncertainty can be processed in the possibilistic setting.

Qualitative decision theory (Dubois et al. 2001; Fargier and Sabbadin 2005) is also worth mentioning. Ordinal possibilistic substitutes to rational decision making criteria under

probabilistic uncertainty can be devised, for the modeling of optimistic and pessimistic attitudes in the face of risk, and for one-shot decisions. These attitudes respectively correspond to computing the possibility and the necessity (certainty) that the chosen decision yields a good result.

Conclusion

This brief introduction to possibility theory does not intend to cover every aspect of the theory and all the issues related to it. It is just a survey of basic notions and ideas underlying it. As suggested above, it is a very versatile tool because it can be purely qualitative (valued on a finite symbolic scale or even just comparative), or fully numerical. Possibility often refers to partial belief, but may be interpreted in terms of degrees of preference. Possibility theory lies at the crossroads of many approaches to the modeling of commonsense and uncertain reasoning: It has close connections with fuzzy set theory, probability theory, non-monotonic reasoning, and belief revision. A strong point of possibility theory at the conceptual level is its ability to deal with imprecision, incompleteness, uncertainty, and fuzziness tainting pieces of information, within the same framework. It can be seen either as a coarse, non-numerical version of probability theory, or a simple approach to reasoning with imprecise probabilities, or yet a framework for reasoning with extreme probabilities (Dubois and Prade 1998).

Appendix/List of Symbols Used

π	possibility distribution
L	scale, here $L = [0, 1]$
S	set of potential states of affairs
$\emptyset$	empty set
Π	(weak) possibility function
N	(strong) necessity function
Δ	(strong) possibility function
∇	(weak) necessity function

Possibility Thinking

Yu-sien Lin

University, Taipei, Taiwan

Abstract

Possibility thinking is a term proposed by a UK researcher Anna Craft (1961–2014) to describe creative abilities and qualities valued in the field of education. Therefore, it is closely related to the concept of “little c creativity,” and ordinary, everyday, or democratic creativity, in contrast to the “big C creativity.” The approach of nurturing learners’ possibility thinking through education generally adopted two premises of creativity: Creativity can be developed, and all individuals have the potential to be creative. In the early stage of developing the concept by Craft and her colleagues, nine qualities of possibility thinking were put forward, involving self-determination and direction, innovation, action, development, depth, risk, being imaginative, posing questions, and play. In addition, useful pedagogical strategies to foster these qualities have been

documented – for instance, standing back, profiling learner agency, and creating time and space. Based on the premises and pedagogical principles of possibility thinking, more research explored how learners, from early year to primary and secondary education, manifest the features of possibility thinking in their learning. Other research identified the connection between possibility thinking and children’s creative learning process, or identified the pedagogical strategies in different areas, such as dance, art, drama, mathematics, or science, that foster learners’ possibility thinking. Albeit the life of Anna Craft came to an abrupt end in 2014, the critical notion of possibility thinking may continue to offer its useful insights in educational practices, as well as research, as long as exploring possibilities remains fascinating.

Situating Possibility Thinking in the Research of Creativity

The notion of “possibility thinking,” although informed by creativity research in the psychological field, is not a psychological term but a term proposed by a UK researcher Anna Craft (1961–2014) to describe the creative abilities and qualities valued in the field of education. It is closely related to the concept of little c creativity, which recognizes the creative potential of ordinary people and the possibility that creativity can be nurtured through education. Creative abilities such as imagination, posing questions, and play are considered main elements of possibility thinking demonstrated throughout an individual’s creative engagement with the environment by asking the question: “what if.” Possibility thinking presents a clear opportunity to integrate creativity and the possible as a field of inquiry (Glăveanu 2018). Possibility thinking, or *what if* thinking, was put forward in the late 1990s in a

creativity discourse which Jeffrey and Craft (2001, p. 1) described as “a universalization of the conception of creativity,” and that highlighted the relation between economy, labor force, and individual creative capabilities. This chapter explores the connection between possibility thinking and creativity within the field of the possible.

A Brief History of Creativity Research

Creativity is embraced broadly, as a capacity for coping with life’s problems effectively, and is seen as a necessity for all, rather than the rare gift and a luxury for the few (Craft 2005; Jackson et al. 2006). Enhancing creativity became one of the salient objectives in education at the turn of the twentieth century and remains a focus into the twenty-first century. This discourse around creativity is different from those formed in the history of creativity research in western societies.

For instance, Plato’s argument predominated in the past, suggesting the source of artistic and creative expression was divine intervention, a mystical source of human inspiration (Sternberg 2003). This general concept of creativity had not receded until the Renaissance and the Age of Enlightenment, when people started to look for the source of creativity in the inner self of individuals (Hammer 2002). By the end of the nineteenth century, varied definitions and research themes focused on creativity had evolved. Specifically, five main themes within creativity literature in the nineteenth century can be summarized (Becker 1995) as follows:

1. How is creativity defined?
2. Who has creativity?
3. The characteristics of creative people.
4. The appropriate uses of creativity.
5. Can creativity be increased through conscious effort?

Though creative genius became the major theme of research and the belief that creativity was the inherited ability of prodigies predominated (Hammer 2002), these questions and themes continue drawing the attention of creativity researchers nowadays.

In the first half of the twentieth century, a shift occurred in both the research approach and research topics. Four major traditions emerged in psychological studies of creativity, and each represented distinct views of the human mind and explanations of creativity (Ryhammer and Brodin 1999). The psychoanalytic tradition conceived human's drives (such as love or power) or unconscious conflicts as the source of creativity. The cognitive tradition explored the relation between creativity, intelligence, and giftedness or focused on individuals' creative processes. While the behaviorist believed creative behavior and personality can be conditioned by external factors, the humanistic tradition described creativity as a part of human nature and the innate need to experience higher values that fulfill individuals' lives. Rather than focusing on external regulation and coercion to achieve creativity, humanistic psychology has emphasized the importance of autonomy and individual growth within education and personal development.

Insights from theoretical and empirical research continued to inform the framework of creativity studies from the second half of the twentieth century, onward. By the 1950s, substantial empirical research of creativity was conducted and can be categorized into six approaches: pragmatic, psychometric, cognitive, social-personality, evolutionary, and confluence (Baer and Kaufman 2006; Sternberg 2003). Notably, some of these approaches contributed important ideas and momentum to the rhetoric nowadays of nurturing children's creativity through education.

For instance, the **psychometric approach** measures cognitive abilities, such as divergent thinking, involved in the individual's creative process, as well as personal traits that affect creative orientations, such as curiosity, and being attracted to novelty (Sternberg 2003). In addition to identifying creative cognitive abilities, the **cognitive** researchers also analyzed the thinking process and mental representations underlying creative thought (Baer and Kaufman 2006). These research attempts of conceptualizing creativity as different cognitive abilities or personal dispositions shed light on the research of possibility thinking, which related to and enhanced the

cognitive and psychometric perspectives in creativity research by focusing attention on the capacity of individuals to see beyond what is or has been and find new solutions.

Due to the interest of developing individual's creative thinking skills, certain training programs were proposed, including the thinking tools (six thinking hats) suggested by Edward De Bono (1985) and brainstorming techniques which have been widely applied and researched (Fryer 1996; Parnes 1963; Sternberg 2003). The assumptions and techniques these creativity training programs promoted were described as the **pragmatic approach** and have generated implications for both school teaching and organizational training. Another approach, the **social psychological approach**, also generated implications for fostering creativity by exploring the relationship between personality traits, the social context, and creativity. A diversity of personality traits associated with creativity were identified, such as self-confidence, openness, spontaneity, and risk taking (Baer and Kaufman 2006; Hennessey 1995, 2007). Each of these approaches suggests different ways that possibility thinking arises in the creative process of individuals and is explored in research.

An important distinction was made by creativity researchers between "big C" and "little c" creativity (Craft 2001b; Gardner 2004), which offered support to the concept of possibility thinking as an entry point for everyday creativity. Big C creativity indicates the influence of individuals and their work in society and culture, and little c creativity targets the everyday creative attitudes, thinking, and behaviors across domains in life, such as "what if" possibility thinking. Some researchers termed the two ends of creativity as "high creativity" or "historical creativity" and "ordinary creativity" or "democratic creativity." High creativity gets recognized by experts and demonstrates paradigm-shifting impact within the culture (Boden 2001; Csikszentmihalyi 1996, 1999; Feldman et al. 1994). Ordinary creativity (NACCCE 1999; Craft 2001a, 2005) focuses on the agency and potential of ordinary people to be creative when facing everyday problems (Craft 2001a, b). In some way, product-oriented

creativity perspectives share the same view of big/high c creativity in terms of the criteria and method of judging creativity, whereas little c creativity is not necessarily linked with a product outcome. Thus, the debates and distinctions gradually led to the discussion of the kind of creativity that is more valued in the education setting. These debates and complementary perspectives have continued to generate new possibilities in the field of creativity, including the concept of possibility thinking.

Creativity in Education

Before discussing possibility thinking, it is important to understand how research and conceptualization of creativity has intersected education. As mentioned, the connection between creativity and education can be traced back to the debate about whether creativity can be developed through education (Becker 1995; Esquivel 1995). Creativity research shifted focus to ordinary people inside and outside education while the movement toward child-centered and innovative pedagogy built momentum after the 1950s. Alongside those shifts, more calls for reforms to traditional school practice and curriculum followed, particularly in the USA and UK (Craft 2001a; Esquivel 1995). Creativity research in scholarly fields, such as psychology, and the child study movement played a role in this shift in education (Feldman and Benjamin 2006) through concerns about techniques and approaches. For instance, John Dewey's (1964) advocacy of children's play became influential. The Piagetian cognitive-developmental programs encouraged children to generate original ideas and built momentum. Montessori's approach emphasized the importance of self-expression for fostering creative skills. Lev Vygotsky's cultural-historical theory emphasized the social process in child development (Craft 2001a; Esquivel 1995; Fryer 1996). However, the educational reforms informed by the theories and practices of creativity waned due to widespread critique of child-centered practices, which was fueled by an apparent decline in academic performance (Craft 2001a; Esquivel 1995; Feldman and Benjamin 2006). During the last decade of the twentieth century, creativity was

once more recognized as an important aim of education.

The approach to creativity in education, from the 1990s onward, has been distinct from the past. Although mainly drawing from existing theories of scholarly research in creativity, such as cognitive, social-psychological, or humanistic approaches, the approach, as Craft (2005) suggested, was revolutionary and confrontational, challenging accepted norms and practices in education. Still underway three decades later, the focus continues to target how creativity must be considered in relation to knowledge, curriculum, and pedagogical strategies in order to create an educational setting conducive to creative development.

Reflecting rapid social and economic changes, creativity has become a survival capacity to thrive in this ever-evolving world. The need to grow human capital – young people's competitiveness – by fostering creative capacities through education was highlighted and prioritized at the onset of the twenty-first century (Choe 2006; NACCCE 1999; Thornburg 2002). The premise that creativity can be developed, that all individuals have the potential to be creative, and that creative potential is vital for individual and societal success underpinned the new approach to connect creativity and education (Craft 2001a; Esquivel 1995; Feldman and Benjamin 2006; NACCCE 1999). Informed by this frame and urged by social need, curriculum reform was carried out to include creativity as an educational aim in education policy in western countries, including the UK (Feldman and Benjamin 2006; Craft 2005; Shaheen 2010).

The attempts to reignite creativity in education in England in the early twenty-first century (Craft 2005) were attributed to the report "All our future" of National Advisory Committee on Creative and Cultural Education (NACCCE 1999), which advocated a "democratic notion of creativity in learning and pedagogy" (Craft et al. 2013). The impetus initiated by the NACCCE was followed by further development of other policy and attention to creativity in the curriculum, including the National Curriculum. Innovative teaching and teaching for creativity in schools were encouraged, as well as the integration of

the arts and culture into education through initiatives, such as the Creative Partnerships project (Craft et al. 2007) which involved arts practitioners, schoolteachers, and researchers. Although in 2010 the education policy in England experienced a shift of values and perspectives due to a change of government, the commitment to developing creativity of students from early years to secondary education continued (Craft and Chappell 2016). Across these initiatives in policy and education, there was a common committed advocacy for “little-c” creativity (LCC; Craft and Chappell 2009), “the kind of creativity which guides choices and route-finding in everyday life” (Craft 2000, p. 3). Within this strand of nurturing LCC; Craft (1999, 2000, 2001a, b) proposed the notion of “possibility thinking” as the “engine” of creativity (Craft 2000, p. 7) as well as to illustrate the features of LCC. She framed the notion as relevant to both convergent and divergent thinking and refused to confine it to arts-related domain (Craft 2000). Possibility thinking, thus, became a new approach to inquiry and practice to understand and operationalize creativity in education.

Research of Possibility Thinking

Since the mid-1990s, a series of studies explored the concept of possibility thinking (PT), which can be divided into three stages (Craft and Chappell 2016; Craft et al. 2013).

In the earliest phase of PT research, mainly conceptual work, Craft (2000, 2001a) and her colleagues focused on theorizing aspects of creativity in education, for instance, teachers’ conceptions of creativity, and what type of creative development should be valued (Craft 1999, 2001a; Jeffrey and Craft 2001). PT was conceptualized as the core of LCC, involving three clusters of abilities – questioning, imagination, and combinatorial play – that manifest the aspiration of asking the question “what if” when facing blockage. Within these three aspects of creative engagement with problems and challenges, nine qualities were proposed to observe classroom practices as well as children’s learning: self-determination and

direction, innovation, action, development, depth, risk, being imaginative, posing questions, and play (Craft 2001a, b). In this first stage (2002–2006), the enquiries focused on PT and pedagogy with children from 3 to 7 years old. Several interlinked features of classroom teaching that nurture children’s PT were identified, including teacher’s standing back, profiling learner agency, and creating time and space to encourage children’s engagement and exploration in learning (Cremin et al. 2006). The characteristics of PT demonstrated in children’s creative engagement at this stage were refined as posing questions, self-determination, intentionality, play, immersion, innovation, being imaginative, and risk-taking.

In the second phase, according to the review of PT research by Craft et al. (2013), the conceptual studies shifted into empirical work around 2002. The second stage of PT research from 2006 to 2007 focused on the specific feature of PT called “question-posing,” manifested by children 5–7 years old in a playful and enabling learning environment. The core components of PT identified in Stage 2 were question-posing (Q-P), question-responding (Q-R), being imaginative, risk-taking, action/intention, self-determination, play, and immersion. Among the components, play and immersion were found to be salient elements to provide the context for PT. The learning process was characterized by children taking intentional action (i.e., action/intention) and infused with autonomy and agency (i.e., self-determination).

In the third stage (2008–2012), further research was carried out to explore children’s Q-P and Q-R. That research identified a variety of question types that reflected children’s Q-P and Q-R (Chappell et al. 2008). In addition, PT research returned to the early focus about the nature of PT and the pedagogical strategies teachers adopt to foster PT. In this phase of the research, work with pupils aged 9–11 broadened the developmental understanding of PT. Several studies focused on defining types of relations between Q-P and Q-R, as well as other characteristics of PT. That research confirmed the significance of children’s verbal and nonverbal questioning in their creative

learning (Chappell et al. 2008; Craft et al. 2013) and highlighted the importance of imaginative and playful behavior among older children (Craft et al. 2013). One of the features of PT, “risk-taking,” defined as the quality of moving into an unknown space with courage (Burnard et al. 2006), could not be observed among older children aged 9–11 (Craft et al. 2013), and the same result occurred in a more recent study with adult participants (Craft and Chappell 2016). However, “risk-taking” was identified as one of the core features of PT in another study in this stage about the play in younger children (4 years old, Craft et al. 2012). By reanalyzing the research data of earlier studies spanning the whole primary age range, a study by Cremin, Chappell, and Craft (2013) reported the inherent role of narrative storytelling of children in shaping their questions and imagination, leading to their “as if” thinking.

From 2012 onward, the studies extended conceptualizing of PT, broadening the population of research participants, and contributed new research findings to the field. First, PT was conceived in previous studies as “what-if” and “as-if” thinking, representing the action of asking the “what if” question and driving creative changes to take place. Nonetheless, Craft et al. (2013) started to consider the potential influence of PT and linked it to the concept of wise and humanizing creativity (WHC; Chappell and Craft 2011), which is believed to be able to generate a “quiet revolution,” a kind of “social change valued by the community as a whole in which participants play co-emancipatory roles” (Craft et al. 2013, p. 540). Framing PT as the catalyst of social change, PT researchers began to explore at a small scale how schools, particularly the head teachers, engaged in school change through the frame of PT (Craft and Chappell 2016). Unlike earlier PT studies focusing on the creative engagement of children from 2–11 years old, the recent study in 2016 shifted its attention to adults’ creative response in a broader educational context. This research reinforced the role of QP and QR as well as other features of PT, including imagination, self-determination, action/intention, innovation, and narrative. However, risk-taking was not clearly

demonstrated by the head teachers during their own quiet revolutions to bring about positive change in their schools. Play and immersion were deemed as contextual features (the features that were embodied in the enabling context that encourages PT) rather than core features (the features of PT framing the creative changes in the schools) in this study. One emergent feature, collaboration, however, appeared to drive creative change, which reflected the findings of several past studies (Craft et al. 2012, 2013; Craft and Chappell 2016). Collaboration among peers enhanced the conditions and potential of PT for teachers.

The review of PT research explored thus far characterizes a linear timeline with shifts and growth in research focus and conceptualization of PT. Within the curricular context, research has explored the nature, development, and catalyst of PT in early year, primary, and secondary school teaching. If being categorized by research focus in different learning areas, PT has been explored within mathematics (Clack 2011; Craft et al. 2013), English (Craft et al. 2012; Cremin et al. 2013), geography, science, art (Craft et al. 2013; Pavlou 2013), museum education (Gregoriou 2014), dance (Chappell 2006; Craft and Chappell 2009), and drama (Aristeidou 2013; Lin 2010, 2014). Findings reported from these studies form or support the previous understanding of the characteristics of PT, particularly manifested in varied creative learning contexts. Some findings among this research contribute to identifying peer collaboration as an emergent feature of PT and confirming the relationship between narrative, imagination, and questioning. Other findings generated pedagogical implications of nurturing PT through teaching creative dance movements, drama activities, or linking resources like interactive museum visits, as well as generating insights and new possibilities of hybrid pedagogy for fostering PT in different sociocultural contexts such as an Asian context.

If looking at the development of PT (see Table 1), it was first theorized by conceptual work as the core aspect and engine of little *c* creativity, concerning ordinary people when coping with everyday life challenges, and later explored

Possibility Thinking, Table 1 Nature and characteristics of PT

Stages		Components
Earlier conceptual work		Self-determination and direction, innovation, action, development, depth, risk, being imaginative, posing questions and play
Empirical work	Stage 1 (2002–2006)	Posing questions, self-determination, intentionality, play, immersion, innovation, being imaginative, and risk-taking
	Stage 2 (2006–2007) and Stage 3 (2008–2012)	Question-posing (Q-P), question-responding (Q-R), being imaginative, risk-taking, action/intention, self-determination, play, and immersion
	Studies since 2012	Q-P, Q-R, imagination, self-determination, action/intention, innovation, narrative, and collaboration

empirically regarding how it is manifested or nurtured during creative engagement in an abling context, mainly in early-year and primary education. The research population was broadened recently to adults and the research implications, therefore, broadened to concerning wise and humanizing creativity valued in the community. The specific context in which PT arose held a different discourse around creativity from the historical context that formed creativity research. As PT arose during a period of increasing focus to enhance creative capacities in the broader population, as a form of human capital, little c creativity at different life stages became a shared focus between PT and creativity research. The concept of PT brought a new perspective to creativity research and lead to a new territory of research exploration. The features of PT identified in different research stages have continued to reflect not only the competencies desirable in the educational context, but also the qualities and mindset every individual (from children to adults) needs to thrive in society nowadays to overcome inevitable difficulties and envision new possibilities. The field of PT needs continued work on understanding its developmental nature from the early years to later stages of adulthood – a potential synergy between PT researchers and the possible as a field of inquiry.

Conclusion

Possibility thinking can be considered essential to the possible as a field of inquiry, but research outside of education has yet to develop. Within education, PT research has evolved from creativity research

and helped to understand the key role of question-posing and question-responding in the creative learning process. The concept of possibility thinking was proposed in a universal revive of fostering creativity through education at the turn of the twentieth century. Creativity was reconceptualized then as a capacity for coping with life’s challenges and problems effectively, and as a necessity for everyone to thrive. Enhancing creativity through education to raise competitiveness and economic performance became a salient objective, particularly in the context of the UK. This social and political discourse promoted little c creativity, a democratic notion of creativity, in contrast to an earlier emphasis on big C creativity. Within this strand of nurturing creative potential, Craft proposed PT as a core part of the creative process, conceiving of PT as the aspiration of asking the question “what if” when facing everyday problems, building from three clusters of abilities involving questioning, imagination, and combinatorial play.

Since 2002, empirical studies have been conducted to support the earlier conceptualization of PT, and the research foci mainly explored the nature of PT and the undergirding pedagogical strategies that foster PT in the education of early years, primary, and secondary school. The characteristics of PT were further developed and refined as the studies moved into different stages. In more recent years, the PT researchers extended the conceptualization of PT by connecting it with the concept of wise and humanizing creativity (WHC) and looked at how adult participants manifest PT when engaging in school change. Although the life of Craft came to an abrupt end in 2014, the notion of possibility thinking may

continue to offer a useful framework for inquiry into the possible across many fields and domains, including educational practice.

Abstract

Winnicott was a British psychoanalyst famous for identifying an area of experiencing between inner psychic life and social reality called the potential space. In his work, potentiality is what can emerge on the basis of what is already there, or, in other words, it is there, where new possibilities can emerge. The idea of potentiality – and a practical concern with the possibility of possibility – can be found at the heart of all aspects of his work. First, as a researcher, he pragmatically expanded the psychoanalytical tradition on the basis of his unique clinical experience. Second, as a theoretician, he developed an understanding of human development whereby the child emerges as a person within a good-enough environment, and, in a first phase, differentiates from the carer thanks to a complex and paradoxical process of self-formation through symbol use. These observations led him to propose the ideas of transitional phenomena or potential space. What might be called “potential phenomena” (or phenomena of potentialization) mark the beginning of symbolism in the play between infant and carer and evolve via more elaborate child's play into the cultural experiencing and creativity that can continue throughout adulthood. Third, in his clinical work, Winnicott considered psychotherapy as a technique for creating a potential space to engage in a form of shared play. For children or adults who lacked the possibility to play, these therapeutic spaces aimed to provide a good enough environment – institutional, relational – within which the person can come to experience phenomena of potentialization which render the possible, possible.

Introduction

Donald Woods Winnicott was born in Plymouth in 1896 and died in 1971. His higher education at Cambridge was interrupted by World War I, and he became a medical trainee in a temporary hospital before becoming a medical officer on HMS Lucifer, a Royal Navy destroyer. His subsequent clinical training at St Bartholomew's, London, included a phase during which he was influenced by his reading experience of Freud's *Interpretation of dreams* (Freud 2001), and after being analyzed himself he became a core member of the "independent" tradition of British psychoanalysis.

Always respectful of and influenced by the two intellectual traditions of Freud and his followers as well as of Melanie Klein and her group, Winnicott nevertheless pursued his own direction in psychotherapy, and his highly original reflections and theorizations were thoroughly grounded in his extensive clinical experience with children, adults, and fellow professionals.¹ Perhaps, Winnicott's most influential original contribution, and certainly the most relevant to the theme of "possibility," is his theory of transitional phenomena.

His initial essay on transitional objects and transitional phenomena dates from 1953 and was republished in 1971, the year of his death, as part of a wider volume *Playing and reality*, which connects transitional phenomena to crucial topics such as playing, dreaming, fantasizing, cultural² experiencing, and creating more generally. In remarks scattered throughout this volume, he

makes clear exactly how and why his thinking about transitional phenomena differs from existing psychoanalytical theory. Without documenting these remarks here, the crucial difference concerns what Winnicott calls the *location* of transitional phenomena including playing with, and among children, and cultural experiences among adults.

That location is neither "inside" the mind of the individual nor "outside" in reality. Rather, such experience unfolds precisely *between* individual and world such that "the behaviour of the environment is part of the individual's own personal development" (Winnicott 1991, p. 72) and therefore must be included in any adequate description of human emotional development. During infancy, that behaving "environment" is constituted by the primary caregiver, and Winnicott refers to this ambiguous and ambivalent "location" between "the mother and the baby" as the *third area* or the *potential space*. Obviously, all sorts of essential activities happen between caregiver and infant (feeding, clothing, cuddling, and communicating), but for Winnicott an essential possibility afforded by this potential space is for play to occur, but – as summarized below – this "play" must not be understood in a trivial manner. First, play is neither part of external reality nor internal reality but is *at play* between them, and second, it is thus a phenomenon that can never be understood in relation to either the care-giver or to the infant taken alone. Once adequately established, the play that occurs within the potential space forms the basis for any forms of vitality, creativity, symbol use, or "cultural experience" – such as they are – that continue to exist within the lives of adults.

Playing, for Winnicott, is thus directly connected to creativity, and he insists that without play there can be no creativity, and without creativity there can be no self-discovery. The third or potential space is the place wherein imaginative possibilities and symbolic capacities can be cultivated and entertained in a manner that enriches life and renders it flexible enough to reach out from its past to an ever-emerging future. In his 1971 book, Winnicott shows that the potential space, emerging early in development, is not only the basis of creativity in life, but also, of human capacity to enjoy cultural experiences

¹ This included collaborators from all sectors of care, such as nurses, social workers, priests, etc., and also years of work with displaced children and mothers, and with young delinquents in various shelters and camps

² "Culture" here means an ever-expanding pool of inherited tradition including myth, religion, science, games, and the various arts

(listening to music, feeling poetry) and participation to culture – doing art, religion, or science. In effect, in each case, these experiences occur between one's psychic reality and the social world, or also between tradition and one's unique contribution: "*it is not possible to be original except on the basis of tradition*" (Winnicott 1991, p. 134). The traditions of the past allow us to inherit what Winnicott called a *pattern* that, ideally, can serve as the basis for forms of inventiveness that are suitable for present circumstances. In that sense, the potential space is what makes human and social development possible.

The idea of the possible, emerging between tradition and personal creativity, within a potential space, is at the heart of Winnicott's scientific work, his understanding of human development, and his practice as a psychotherapist, as we will now see.

The Possibility of Knowing

The notion of "possibility" (and its close relation "potentiality")³ is at the heart of Winnicott's theoretical elaboration. In his theoretical work,

³ Possibility and potentiality are related concepts, but they can of course also be distinguished. To offer one tentative way of drawing this distinction, to describe something as having "potential," points toward a particular kind of "possibility": that something not yet actual will, or may, become so in the future. An athletic child who is not yet a professional sprinter shows to an observer the potential to become one but may instead become a footballer or perhaps a banker. What they do in fact become is a question of what is made of that potential. Perhaps, with the help of the one who observes it, the potential transforms or evolves or develops or undergoes some process of conrescence through which – *in time* – it becomes an actuality. Not all possibility is of this "potential" kind. For example, when asked by a hungry friend, a person says that it is possible that there is cheese in the refrigerator, but she is not sure. Whether it turns out true or not does not depend on any transformation or evolution or development – *in time* – of the cheese. The cheese is either there or not, and the question of its "possibility" refers only to a lack of certainty on the part of the fridge owner. Winnicott is a thinker both of potentiality and of possibility. One might say that he investigates the potentiality that gives rise to the capacity for the kind of possibility at play in the question: "is there cheese in the fridge?"

Winnicott was both influenced by the pattern proposed by Freudian thought, while also modifying it – patterning it – and *making it his own*.

In his scientific and clinical research, Winnicott was deeply pragmatist in his approach; he would "try" a (Freudian-Kleinian) psychoanalytically inspired interpretation with the parents of a sick child, accepting it as a good enough theory if it worked, but changing it if it failed to account for the reality of infants in their environment (Winnicott 1967a; Zittoun 2015). He made this method of a psychoanalytical search for truth very explicit in a comment from 1942 which shows that he saw his own work as the pursuit of the expansion of the possible, an expansion that is reachable both through scientific investigation and therapeutic work:

Thus search for truth is a cycle of three phases: piecemeal objective observation; construction and testing of theory based on observed facts; and imaginative reaching out in front of accredited theory towards the invention of new instruments of precision, these opening up new fields for objective observation. (Winnicott 1942b, p. 146)

Human Development and the Possible

Human development is far from a relatively simple matter of the biological maturation of self-contained organisms, since it also entails cultural inheritance and the development and mastery of the complex forms of symbolism – and the advanced psychological functions these enable – that mediate all human culture and society. Through his texts, Winnicott expresses a belief in infants' and adults' capacity to develop and grow, and to find ways for growth even in the face of deprivation. "In terms of development it can be said that health means maturity according to the maturity that belongs to the age of the individual (...) The tendency toward maturation is part of that which is inherited" (Winnicott 1967b, p. 66).

However, as Winnicott famously said, there is no such thing as an infant (Winnicott 1960, pp. 587, n4); there is always a child and a mother, a family, a house, a neighborhood – an environment. Hence, development itself needs both this tendency toward maturation, and the forms of

originality (including imagination and symbol use) gradually cultivated within and provided by a “good-enough environmental provision” (Winnicott 1967b, p. 66). This good-enough environment is usually expected to begin within the mother-child (or carer-child) interaction, but it is also something that – all going well – continues to be shared throughout life. In infancy, it is thanks to the availability of the mother (or carer), their handling of the baby, and their capacity to hold it and play with it, that the child can make the experience of feeling sufficiently supported to entertain, explore, and expand its psychosocial possibilities (Winnicott 1967b, p. 77).

More specifically, Winnicott describes the initial process by which the young infant, who is at first incapable of living without a carer, progressively becomes separated from them. Viewed psychologically from the perspective of the infant, this is also a matter of coming to realize that one’s care-giver exists as an entity in some way separable from one’s own being, and indeed that there is a surrounding world of objects beyond one’s immediate needs:

From a start of being merged with the mother the baby is at a stage of separating out the mother from the self, and the mother is lowering the degree of her adaptation to the baby’s needs (both because of her own recovery from a high degree of identification with her baby and because of her perception of the baby’s new need, the need for her to be a separate phenomenon). (Winnicott 1968, p. 224)

This notion of a “merged” mother and baby gets us some way toward understanding what it might mean to speak of a location that is neither subjectively “inside” nor objectively “outside,” but rather *between*. From out of this merger, as it were, the potential space between carer and infant must afford the conditions for the emergence of something like an “individual,” a process of individuation that yields for the infant a sense of a self relatively distinct from others and from its environment. In Winnicott’s description, during the initial merged state the mother adapts herself to the baby’s needs, feeding when hungry, changing when soiled, soothing when in distress, and so on. Taking the infant’s perspective, this creates an almost magical experience of satisfaction that

Winnicott calls “omnipotence.” But seen from another perspective, this magical omnipotence is a carefully contrived illusion that is made possible by the mother’s caring attention whereby she provides what is needed just as it is wanted. It is the mother, who of course is already an individual with a self, who creates this magic by mediating the illusion in which desire is met. But, as the baby’s needs and capacities change with gradual development, so the mother lowers the “degree of her adaptation,” an adjustment which affords the infant a degree of disillusionment. But this disillusionment is not simply negative from the infant’s perspective, because it invites them to a growing sense of an external world, and along with that, a growing sense of being a self within that world. In other words, the disillusionment affords encounters with a world that need not only meet one’s desires, but that can also frustrate, disappoint, and be grappled with and learned about.

It is here that Winnicott gives a distinctive meaning to “play.” For the process of disillusionment to be a positive and not a traumatic experience, the mother and infant *play* with the relationship between illusion and disillusion. The place of play is thus neither “inside” (it is not a subjective illusion under the spell of complete magical control) nor “outside” in the repudiated world that has been recognized as “not me” (because it is beyond magical control). What the play between mother and infant plays with is precisely the play between illusion and disillusion, inner and outer, doing and being done to, and omnipotence and dependence, and this play unfolds in a safe-space in which these paradoxes remain unchallenged and happily tolerated. The situation in which the mother mediates the “illusion” of the merged state gives way to a situation in which the two are both merged and not merged, and it is at this point of development that one tends to see a new form of mediation crystallize into the form of what Winnicott calls a “transitional object”: the infant’s *first “not me” possession*, their first *symbol*, and a *plaything* whose importance will continue to linger as they grow.

Since transitional objects are precisely indeterminate as to their inner/outer, me/not me nature, they tend to have features which afford

this ambiguity: a corner of a blanket or a rag doll that – along with the thumb – might be in the mouth and then out of the mouth, for instance. This feature affords the *potential* for the transition object to appear to the infant one moment as a part of “me” and the next as an external object, perhaps under my control, but also existing without me. For the same reason, being a perceptible object which remains despite these shifts, the materiality of the transition object can also serve as a primitive *symbol* as it comes in this way to acquire and carry a basic *meaning* (associated with a sense of importance) for the infant. The transition object thus comes to carry the meaning of a thing that “speaks” of a me and a not me, or of a thumb that remains even if it is no longer being sucked, and also perhaps of a mother no longer here, but who will nevertheless return. As the child grows, transition objects can continue to be important, as when Winnicott writes of 2-year-old Edmund playing with a piece of string during a consultation with his mother, and using the string as a plaything to manage his need for her in a way that symbolized both “separateness and union through communication” (p.43). The string – being something that “both *joined and separated*” (Winnicott 1991, p. 108, emphasis original)⁴ – served as a plaything

precisely because it so effectively symbolized *for* the child a predicament that can in this way be playfully *handled*.

Winnicott thus considered that many possible things or objects could be used in this potential zone, as transitional objects – a thumb, a blanket or a teddy bear, or even a sound; each child may thus use any object in this function of being in between, me not me, and created yet found. At some point of her development, the child can start to live with this experience of being separated from the carer, and the object that symbolizes the junction may become less important – perhaps only used some sad evenings to fall asleep. Eventually, the corner of blanket or the teddy bear will become just a mere blanket – deattached, it will fall back into the “limbo of half-forgotten things” (Winnicott 1959, p. 526). Yet when this happens, the child has in some ways internalized the symbolic and playing function and can reactivate it in many other, less vital situations, along his development and socialization – in playing and games, joking, and reading. It later will be part of one’s capacity to daydream and dream, of one’s daily creative capacity – the ability to see the same tree every time anew – and adult cultural experiences:

Put rather crudely: we go to a concert and I hear a late Beethoven string quartet (you see I’m high-brow). This quartet is not just an external fact produced by Beethoven and played by the musicians; and it is not my dream, which as a matter of fact would not have been so good. The experience, coupled with my preparation of myself for it, enables me to create a glorious fact. I enjoy it because I say I created it, I hallucinated it, and it is real and would have been there even if I had been

⁴The famous paper on transitional phenomena and transitional objects makes no mention of the concept of potential space, but this concept is elaborated in other parts of *Playing and reality*, especially Chapter 7 on *The location of cultural experiences*. The concept of potential space is a development and refinement of the concept of the “intermediate area of experiencing” (sometimes “third space”) discussed above as the place for transitional phenomena. In other words, it is a paradoxical “area” which exists “between” subjectivity and objective perception, and hence an area in which no clear distinction is drawn between what is really “out there” and what is merely “in here.” The main thesis of this chapter, elaborated on page 135, is divided into five points. First, that playing is the initial manifestation of cultural experience of all kinds, and that it happens in the “*potential space* between the individual and the environment (originally the object).” Second, how a given individual *uses* this potential space will depend upon early life experiences. Third, that experiences within the potential space tend to be “maximally intense” since they concern the interplay between an omnipotent sense of there being “nothing but me” and the realization

that objects exist “beyond” me. Fourth, that the quality of these experiences are contingent upon a *feeling of confidence* that comes from the dependability of the caregiver on whom the infant depends (and who more or less tolerates the potential space as a place for play). And finally, that therefore any study of the play or of the cultural life of an individual requires insight into the fate of a potential space that will be in some sense “sacred” for them. Through these means, Winnicott shows how his theory of transitional phenomena is connected to an account of the origins of cultural experience in play – play in turn being an experience of transition that is rooted within experiences of transition

neither conceived of nor conceived. (Winnicott 1959, p. 527)⁵

Hence, Winnicott's potential space is the condition of the possible in multiple senses. It is potential, not only because it enables the child to develop as an independent being, but also because it is the beginning of the zone, or area, or types of experience from which symbolizing, playing, and cultural experience will emerge. For Winnicott, then, the meaning of "potentiality" (afforded by means of the transitional phenomena) is this *journey toward experiencing*.

This "intermediate area of experiencing" that is the *potential space* serves for Winnicott as the source of creative living as such, and the sphere from which religion, philosophy, and the arts spring and are continually replenished (Stenner *In preparation*; Zittoun 2013).

On Making the Potential, Possible

Winnicott's optimism and fundamental belief in the potential for development combines with his practical endeavors to construct – by means of psychotherapy – new spaces of potentiality which can serve to supplement and support those whose capacity to play within a third space has been compromised or hindered (either by lack of adequate prior experience or challenges from life events). In his work, he explored many "technical" ways by which the possible can be

potentialized.⁶ Winnicott indeed believed that even people who did not have the safe experience of a good-enough environment – because of the lack or inadequacy of the carer, often due to causes difficult to master – and therefore, who were not able to experience potentiality or play, could be given another chance to develop them. Interestingly, Winnicott saw institutions, healthy relationships, and the therapeutic space, as offering such a sense of the possible when carefully managed. We offer three short examples, involving infants, adolescents, and adults respectively.

First, in his early work, Winnicott shared many observations of various carer/child interactions that were made at his consultation reception at the children's hospital. A series of very short vignettes describe Winnicott's observations of mothers and young infants entering the room, sitting opposite him, and reacting toward a spatula left on the table (Winnicott 1941b, 1942a). Usually, the mother lets the child explore more or less trustfully; he or she typically first hesitates and holds back despite signs of temptation, looking to the adults for approval, before eventually daring to let their desire guide their action, and so, after salivating, putting the spatula in their mouths; and then, playing with it, throwing it on the floor, or banging it, until they become interested in something else. Around this small scene, Winnicott observes many variations in children's exploration and trust; and children coming with various ailments – asthma, anxiety, or others – very often see their symptoms disappear after a few sessions, in which, if not the parent, then Winnicott himself holds the child on his lap and tolerates all the hesitations, fears, excitement, aggressivity, and inner-conflicts of this small baby exploring his or her desire to play with the spatula (Winnicott 1941b). What he here does, in a few sessions, is restore the basic sense of trust of the child in their environment by supporting their exploration and enjoyment of the world. In these early papers, Winnicott has not yet named potential

⁵ Thus, cultural experiences – experiences of pieces or arts, religious experiences – emerge out of several features of transitional experiences, such as: the deathection of an the initial transitional object (not fetish); the extension of the symbolic function to many objects which with can be played; the development of the symbolic function itself; the ability to use objects, and to fantasize, and; the ability to relax, and let oneself go on an unintegrated state. These must then be linked to, and converge with: the complication of the cognitive abilities of the person; the complexity of the socialization of the person; (the entering in highly structured social areas), and; the complication and diversification of the emotional experiences. All these things become combined and infinitely declined, according to one's interest, and become the reality of human cultural experiencing

⁶ In this respect, Winnicott can be considered an important innovator of what Niels Akerstrøm Andersen has called "potentialization technologies" (Åkerstrøm Andersen and Stenner 2019)

phenomena, but he has already identified the conditions of possibility of their emergence, and the profound importance of play. In effect, in this early work, Winnicott creates the relational conditions for the infant to be able to use objects in a potential zone, and play with them – even if this can be lost and may need to be reconquered again.

Second, Winnicott was brought to work in Q Camps, a residential facility for young delinquents during World War II (Reeves 2017; Winnicott 1941a, 1943) as well as hostels for homeless children (Winnicott and Britton 1944). This brought him to reflect on the therapeutic role of the environment in supporting the delinquent or homeless child's otherwise interrupted development. His basic idea was at that time, as we have seen, that a good enough home gives the child the basic security and trust that he or she needs to develop; that home also welcomes the child's exploration, and contains and absorbs the child's developing needs, including to attack and destroy. During the war, children separated from their homes, sometimes for long periods, could adjust to further environments depending on this; "if the parents are proved to be trustworthy, the child has every reason to believe that other people may be the same, so that he can face life in an optimistic way" (Winnicott and Britton 1944, p. 305). In contrast, a child becomes delinquent, because the home – for whatever reason – failed to contain or absorb the child's necessary anger or destructiveness; consequently, "the child has to seek and test the ability of the structure of society" (Winnicott 1943, p. 198). In other words, "according to this view the delinquent's anti-social acts are (like so many symptoms in psychology) a symptom of hope, representative of the forward emotional relationship which the child is trying to hold" (Winnicott 1943, p. 198). Hence, even – or perhaps especially – deprived children manifest their need to find a better environment. Consequently, Winnicott conceives of institutions such as hostels for homeless children, of which there were so many during the war, or for delinquents, as a "substitute home"; "each hostel tries to reproduce as nearly as possible a home environment for each child in it" (Winnicott and Britton 1944, p. 305). This is made possible,

first, by a careful distribution of role between psychiatrist, psychiatric social workers, and hostel staff. Second, concretely, a frame is provided offering not only shelter, clothes, regular meals, and schooling, but also "apparatus and ideas leading to rich play and constructive work" (Winnicott and Britton 1944, p. 305). Third, within this space, the children will test the hostel staff, or bring other children to test them; they may destroy things, or attack staff members, or create disputes between staff. This is where the staff play a key role, in welcoming yet resisting the attacks, without sentimentality, knowing that it is part of the process of development of the child (Winnicott and Britton 1944, p. 306).⁷ Winnicott concludes his report on what he sees as the "war-time experiment" by saying that "it has surely established the fact that in the treatment of children suffering from emotional disturbances, residence in hostels under special management can have definite therapeutic practice" (Winnicott and Britton 1944, p. 311). In the light of his later work, we may say that Winnicott created the frame within which a child was in good enough conditions to be able to play, while exploring the limits of relationships and his inner world, that is, preserving the very conditions of a potential space.

Third, much later and in his practice as an analyst with adults, Winnicott paid careful attention to people's ability to play. Play has great importance for him, because to genuinely play is to create and enter a potential space. Psychotherapy itself "has to do with two people playing together" (Winnicott 1991, p. 51). Psychotherapy can therefore be envisaged as enabling a zone of overlap between the play of the analyst and that of the analysand.⁸ Conversely, the absence of play is the absence of potentiality. Therefore, if play is not possible for an analysand, then the aim of

⁷ Winnicott also proposes to sort children in various hostels according to their needs, whether or not they have had a former experience of a good home, or whether or not they manifest antisocial conduct, together with staff most likely to handle these types of children

⁸ From this perspective, not only does the therapist err if they can only understand such playfulness as infantile regression, but they also miss an essential element for a creative relation to the world

therapy is to occasion an environment in which play becomes a possibility. Winnicott thus reports the case of a woman who does not play – a case presented in the second chapter of *Playing and reality* (Winnicott 2001). Rather than playing, this woman appears as someone who engages in a form of dissociated fantasizing, a private and inaccessible form of daydreaming:

For instance, the patient is in my room having her treatment and a little bit of the sky is available for her to look at. It is evening. She says: "I am up on those pink clouds where I can walk". (...) The patient may sit in her room and while doing nothing at all except breathe she has (in her fantasy) painted a picture, or she has done an interesting piece of work in her job, or she has been for a country walk; but from the observer's point of view nothing whatever has happened. (Winnicott 2001, p. 27)

For Winnicott, this is *not* dreaming or imagining, because it is both only in the mind of the person, and also just in some part not connected to her wider life. What Winnicott calls "fantasizing" can easily be mistaken for the playing or dreaming that happens in the potential space, but it is dreaming that precisely does not put the inner and outer or the self and the other "at play" together. In this sense, the one fantasizing is dissociated: Unlike play or dream, the fantasizing is about nothing and has no consequence. Play has frozen stiff and – as if morphing into a parody of itself – become "locked in the fixity" of fantasizing (p. 42) and dissociated from the living core of the potential space (p. 43). For Winnicott, these dissociations are an important clue explaining why the patient cannot realize her potential: Why she fails her friends and is not using her great artistic capacities, and why she complains that she has always "missed the boat" in her life, as if life were paralyzed and forever stuck in condition of unrealized potential. Winnicott finds an important source of this situation in the woman's childhood as the youngest of many siblings, when she recalls being invited to play in games already set for her, unable to introduce her own innovations into the existing pattern of family tradition. As a result, she was only partly playing, giving those around her the impression she was not really taking part, and giving herself the experience of observing herself as if from the outside. This form of observation then developed into fully fledged

fantasizing, which, far from *connecting* her to the demands of her actual life, served to interfere with any play between dream and practical existence. In short, her fantasizing was not taking place in the transitional or potential area; it was in some part of her mind only.

Winnicott describes a long therapeutic process, in which he offers very long and flexible sessions to the patient, welcoming any material, and reflecting on the distinction between fantasizing and dreaming; at some point, the patient falls asleep in the session and, in the space offered by Winnicott, progressively discovers her own dreaming and how it differs from fantasizing:

The *fantasy* had to do with people coming and taking over her flat. That is all. The *dream* that people came and took over her flat would have to do with her finding new possibilities in her personality and also with the enjoyment of identifications with other people, including her parents (...) [Given the patient's interest for poetry] I said that fantasizing was about a certain subject and was a dead end. *It had no poetic value*. The corresponding dream, however, *had poetry in it*, that is to say, layer upon layer of meaning related to past, present and future, and to inner and outer, and always fundamentally about herself. (Winnicott 2001, p. 35)

Hence, for Winnicott, dreaming, as playing, is something relational and fluid that involves the whole of the person; it is symbolic, in the sense of connecting inner life and outer life, past, present, and future; it is full of potential, in the sense that it opens new possibilities for one's own life, and relationships to others. A dream or playful activity or artwork is, for Winnicott, something that *has poetry in it*, and this means nothing more than that it puts one in contact with the potential space that is the "living core of the personality" (p.43). This case is thus that of someone who lacked access to potential phenomena, and so could not create new possibilities for her life. Winnicott's intervention is aimed at restoring the capacity to engage with the phenomena of potentiality by offering the patient a secure and holding space, welcoming her externalizations, and creating a zone where these could be shared, and played with together in a manner that opened up transitional possibilities.

In any case, Winnicott seemed to be an expert in creating the supportive environments that allow

people to engage in potential spaces, and thus to use objects and create with them – a spatula, a toy, or a dream; he was an expert in making the potential possible, and with it, restoring the possibility of the possible.

Summary

With examples drawn from practice with children, adolescents, and adults, we have briefly described three ways in which Winnicott's practice concerned the technical problem of how to create environments which render possibility more possible. These practices were informed by Winnicott's distinctive psychoanalytical theorizing, at the heart of which were the transitional phenomena which we have shown to be phenomena for and about potentialization. Potentialization phenomena are related to an area/time of experiencing which is located between inner psychic life and social reality and between self and other, and which permit a degree of play between these possibilities and actualities. Potential phenomena mark the beginning of symbolism in the play between infant and carer as the self first emerges and develops, but they evolve via more elaborate child's play into the cultural experiencing and creativity that can continue throughout adulthood. The vital core of the human personality is something that is not personal at all, but which allows the person to continually become what they are and what they might be.

Possible in Anthropology

Sarah Grosso

Webster University Geneva, Geneva, Switzerland

Abstract

Anthropology is the study of people: how they behave, socialize, communicate, and understand the world. Etymologically, the word combines the Greek terms *anthropos* (“human”) and *logos* (“thought” or “reason”) (Britannica), literally meaning the study of humankind. Often confused with archaeology, which studies human society in the past (and is considered a branch of anthropology in the USA), anthropologists are interested in contemporary human society and culture.

The distinct anthropological approach to the study of people is ripe with possibilities; by helping us see the familiar in the strange, and the strange in the familiar, anthropology furthers our understanding of ourselves and of others.

This perspective is made possible by the ethnographic method that distinguishes anthropology from other social science disciplines. In contrast with psychologists who focus on individuals and their character and behavior and sociologists who examine

broader social systems, anthropologists are interested in the interactions between smaller groups of people. These interactions are studied via extensive fieldwork that involves spending long periods of time in intimate contact with the people under study.

By seeking an in-depth understanding of what it means to be human, anthropology contributes to cross-cultural understanding, provides inspiration for social change, and helps build empathy across cultural divides.

Anthropology · Social science · Culture · Possible · Empathy · Ethnography · Qualitative research

Introduction

This entry will start by defining anthropology and the ethnographic method with which it is closely associated. It will then explore what this approach to studying humankind makes possible via a case study drawing on anthropological work on gender and, more specifically, women’s rights. Finally, it will consider the broader contribution of anthropology as an academic discipline, more specifically its potential to provide inspiration for social change, boost cross-cultural communication, and build empathy across cultural divides.

Seeing Like an Anthropologist: The Possibility of Exchange

Anthropology emerged as an academic discipline at the turn of the twentieth century. In the British tradition, social anthropology is often associated with Bronislaw Malinowski, considered the founding father of British social anthropology. Malinowski, a Polish anthropologist, was instrumental in training the next generation of scholars and in developing the ethnographic fieldwork method with which anthropology is associated. Franz Boas played a similar role in the USA shaping the tradition of cultural anthropology (Engelke, pp. 22–23).

The goal of anthropology is to gain an in-depth understanding of what it means to be human. It seeks to grasp both cultural variation and universality: understanding how people from different cultures might see the world differently, as well as what it is that makes us all uniquely human. It is often said that, in the process, anthropology makes the familiar strange, while making the strange familiar.

By challenging assumptions and revealing alternatives, anthropology provides a “profoundly useful way of thinking about the modern world” (Engelke 2017, p. 25). For some activist anthropologists like Graeber, anthropology is also consciously a source of inspiration for social change, and his scholarship is underlined by a “commitment to the idea that the world could possibly look very different than it does” (Graeber 2007, p. 2). In short, anthropology teaches us that it is possible for life to be different.

Consequently, one way in which anthropology is connected with the possible is by challenging unchallenged assumptions and enabling us to see the world from other cultural perspectives. By reading anthropological research, we can learn about other possible ways of being and living. As we learn about other cultures and their values, our own values rarely remain unshaken. At the heart of the anthropological project is, therefore, the “search for new perspectives that open up new possibilities” (Chapter “Inspiration” by Glaveanu, this volume).

Comparison and exchange are key to the development of anthropological knowledge, which is built on a process of exchange between the anthropologist and the culture under study. During fieldwork, anthropologists do not assume that their own concepts and understandings are universal or self-evident. Rather, they question what art, religion, law, or kinship mean from “the native’s point of view” (Engelke 2017, p. 15).

This approach has led to accusations that anthropologists are moral relativists and that they unquestioningly accept problematic elements of other cultures, including extreme instances of violence and discrimination. Anthropologists use relativism as a method, rather than a moral stance, in order to study and comprehend another culture in its own terms. This involves comparing

cultures with the intention of seeing the world from another perspective, rather than judging one culture in relation to another.

This approach allows anthropologists to explore topics, including those which could be seen as morally objectionable. An example of this is the anthropological work that has been done to better understand phenomena such as ethnic or nationalist violence, genocide, torture, and extremist politics (Daniel 1996; Hinton 2002; Kelly 2012; Thorleifsson 2018). This work may also seek to understand the phenomenon from the perspective of the perpetrator of violence, as well as the victim. Crucially, as Engelke has stated: “cultural relativism does not require you to accept everything that other people do that you might otherwise find unjust or wrong” (Engelke 2017, p. 17). Seeing like an anthropologist in this way – by understanding, but not necessarily adopting, alternative points of view – facilitates cross-cultural exchange and dialogue, while challenging our own assumptions and opening us up to new possibilities.

Exchange between anthropologists has also been important for the discipline. While anthropology developed as an academic discipline in the UK and in the USA in the early twentieth century, influential traditions have also emerged in countries from Brazil to Australia (Engelke 2017, p. 30). Numerous subfields have also developed providing the possibility of exchange between anthropology and the law or anthropology and economics, to name but two examples. Anthropological insights have also been harnessed outside academia. While many anthropologists work in academia, others follow careers in “applied anthropology” bringing an anthropological perspective to bear in a variety of sectors from NGOs to the military.

Seeing Like an Anthropologist: The Possibility of New Perspectives

It is the ethnographic approach that enables anthropologists to gain insight into everyday practices that best defines anthropology. Ethnography, which literally means *writing culture*, combines the activity of engaging in intimate fieldwork

with the task of producing a written account of a particular culture based on this research. Anthropologists often spend a year or more carrying out fieldwork. During this time, they observe and interact with people in their own language. Afterward, anthropologists write an ethnography documenting what they have learned based on these observations and experiences. For anthropologists, therefore, there is a particularly close link between research and writing.

This in-depth, bottom-up form of qualitative research is holistic in nature and enables the anthropologist to break down commonly held assumptions and trace connections between spheres of life that are often perceived as being separate. For instance, anthropologists have stressed the close links between economics and kinship, as well as the need to understand economic class in relation to gender, race, and sexuality (Bear et al.). In their *Feminist Manifesto for the Study of Capitalism*, Bear et al. argue that in order to understand capitalism, we need to grapple with the “full range of productive powers and practices through which people constitute diverse livelihoods As they seek to realize the potentialities of resources, money, labour and investment” (Bear et al.). This entails analyzing what happens in the household and within kin relations as being integral to, rather than separate from, the markets. Through this lens, the production of capital equally depends on unpaid, intimate forms of labor such as caring for children or the elderly, forms of labor that are all-too-often gendered. By seeking connections, all aspects of daily life are seen as interrelated, rather than separated into independent fields of study such as economics or kinship.

Although often associated with the study of remote, tribal cultures, these methods are just as relevant to the study of contemporary phenomena, like the latest technologies or the global financial crisis. Contemporary anthropologists are as (or more) likely to be found studying how people experience austerity measures or the impact of social media on peoples’ lives (Bear 2015; Miller et al. 2016). This work highlights how the impact of these policies or technologies

differs for people in different places and groups and can, subsequently, provide valuable insights that can inform future policy reform. Working with a team of researchers exploring social media use in nine different countries, Miller highlights how people use and understand social media differently in different contexts. This allowed him to break down commonly held assumptions such as the idea that social media necessarily makes us more individualistic; social media users play an active role in shaping those meanings, and the impact technology has on their lives (Miller et al. 2016).

We live in an increasingly interconnected world and anthropologists acknowledge that their field sites have been shaken by globalization and are rarely bounded or culturally homogenous (Appadurai 1996). Consequently, while some anthropologists may continue to study tribal and indigenous cultures, they do not perceive these cultures as being separate from the broader global social, political, and economic movements. Today, anthropologists study sites such as refugee camps or courts and increasingly conduct fieldwork across multiple sites (Barbosa 2013; Grosso 2013).

Globalization has also demanded innovation. In her study of capitalism, Anna Tsing explores the global trade in matsutake mushrooms. Rather than being based in a specific location, she followed the mushrooms conducting research with “Japanese gourmets, capitalist traders, Hmong jungle fighters, Finnish nature guides,” scientists and many more actors who could help her understand the global trade in the world’s most valuable mushroom (Tsing 2015). Fieldwork was a collaboration between Tsing and six other anthropologists and took place in the USA, Japan, Canada, China, and Finland. Rather than studying a particular site in isolation, the intention was to trace the connections between this site and others.

Seeing Like an Anthropologist: The Possibility of Change

By studying how things are done in and within different cultures and across time, anthropology

helps break down the notion that certain ideas and concepts are “natural” and immutable; things have been and can be done differently.

Anthropological work on the state helps elucidate this idea. States play a crucial role in our lives; they grant us access to citizenship rights such as healthcare and education. In some instances, states can protect us from harm such as when we call on the services of the police if we are victim of a crime. In other instances, states may incarcerate us if we have perpetrated a crime. Despite this crucial role played by states, most people do not usually question the existence of the state or who or what gives it this power over our lives.

Anthropologists studying the state have:

allowed us to pay careful attention to the cultural constitution of the state: how people perceive the state, how their understandings are shaped by their particular locations and intimate and embodied encounters with state processes and officials, and how the state manifests itself in their lives. (Sharma and Gupta 2006, p. 11)

They have observed and documented the everyday practices through which the state becomes “real” such as interactions with state agents like police officers and court clerks. Anthropologists have approached other institutions the existence of which we take for granted, such as the law or the economy, in a similar way (Bear et al. 2015; Grosso 2013).

The way contemporary anthropologists understand culture is central to this approach. Rather than viewing culture as bounded and static, culture is understood as hybrid, dynamic, and ever changing (Merry 2003). This nuanced concept of culture takes into account the active role people play in constantly reproducing culture in everyday life. First, it means that it can be studied by observing the everyday practices and interactions mentioned above. Second, it also entails the possibility of change; culture is constantly being reconstructed and can, therefore, be reconstructed in different ways. This potential for change is inherent in the following case study that examines how anthropologists have contributed to work on gender and, in particular, on women’s rights.

Anthropology: The Possible and Women’s Rights

Engendering Possibility

Anthropological work on gender and women’s rights provides vivid examples of the power inherent in breaking down common assumptions and opening up alternative ways of living. It also shows the possibilities for change inherent in this model of understanding the world.

Rather than seeing gender as natural, biological, and immutable, in part, inspired by feminist philosophers like Simone de Beauvoir and Judith Butler, anthropologists have stressed the culturally constructed nature of gender. As Moore writes, “the obvious fact of biological differences between women and men tells us nothing about the general significance of those differences” (Moore 1994).

Anthropologists have helped document the ways in which the meaning of gender varies across cultures and historical periods. The anthropological lens has also revealed ways in which women may have power in practice, although they may not be *perceived* to hold power (Herzfeld 1985, Blackwood). Blackwood’s study of an Indonesian village traced the ways in which women did hold authority, despite official representations and discourses suggesting they did not. Although women were predominantly associated with their roles as wives and mothers, women played a significant role in the economy and within the village and were to be respected as sources of wisdom by young women and men alike (Blackwood 1995).

The perception that women hold less power than men is often based on the private/public divide; women are associated with domestic roles in the private realm of the home, whereas men are associated with public roles in spheres such as the economy and politics. Anthropologists have helped to break down the perceived separation between public and private spheres, tracing the multiple connections that link the family, the neighborhood, and the nation. Studies of women’s political activism in Iraq and Egypt have found that informal, interpersonal networks such as

grassroots women's groups can be powerful sources of political participation, questioning the assumption that political participation must take place in formal organizations or parliaments (Al Ali and Pratt 2009; Singerman 1995). This reveals possibilities for action and empowerment for both women and men.

The apparent universality of patriarchal systems breaks down in the face of varied, alternate models of gender and kinship that anthropology has documented, opening up the possibility that there are alternative ways to organize society and gender relations than the patriarchal model that dominates in the West. On this basis, anthropologists have argued that there is nothing natural or predetermined about the subordination of women (Engelke 2017, p. 217). Such a definition of gender is central to feminist projects that seek solutions for injustice and discrimination on the basis of gender; if gender is not fixed, it can change, and this allows for the possibility of resisting gender inequalities where they occur.

Anthropology: The Possible and Women's Rights

Drawing on this concept of culture and of gender, anthropologists have contributed to the study of women's human rights by analyzing how people perceive and experience those rights in practice. They have stressed that gender is central to how an individual experiences the law and is able to gain access to their rights and to justice.

Merry and Coutin's research on women's rights demonstrates the kind of insight that an anthropological approach can bring to issues such as gender-based violence. While discussing the UN's attempts to develop statistical indicators to monitor the extent of violence against women around the world, Merry and Coutin argue that valuable aspects were lost, notably those that are best captured by an anthropological approach:

the complexity of women's relationships, their histories, the interplay of love and fear, and the role of kinship and residence patterns. (Merry and Coutin 2013, p. 5)

Statistics also fail to grasp "the extent to which women's everyday lives and experiences are affected by the possibility and the practice of

violence" (Merry and Coutin, p. 8), anthropology provides the opportunity to capture elements of the human experience that are crucial to our understanding, but difficult to quantify or measure.

Anthropologists can help provide the context for understanding complex social phenomena like gender-based violence. They can also help advance our understanding of the efficacy – or inefficacy – of potential solutions. To Merry and Coutin: "violence against women must be viewed in the context of a range of relationships, events over time, and meanings of masculinity and femininity, intertwined with ideas of race, class, region, and so on" (Merry and Coutin 2013, p. 5). These same factors shape the possibility of survivors of violence finding justice: whether (or not) they will have the courage to appeal to the police or a court, how they will be treated if they do, and how they will experience and navigate the court system to, potentially, find justice (Merry and Coutin 2013; Grosso 2013). Anthropologists have, therefore, helped break down the misnomer that "culture" is somehow separate from the law, demonstrating that the law and culture are not only connected, but that culture plays a central role in the development of and the operation of the law and its ability to bring justice.

Summary: Another World Is Possible

Anthropology can be viewed as a social science that aims to explore and document possible ways of imagining and constructing human life and relationships. In this way, anthropology is all about the possible: breaking down deeply held assumptions and commonly held beliefs, seeking inspiration in culturally diverse ways of doing, and thinking and opening up the mind to previously undiscovered or unrealized possibilities. In the words of anthropologist, David Graeber, anthropology:

opens windows on other possible forms of human social existence Human possibilities are in almost every way greater than we ordinarily imagine ... Anthropology also affords us new possible perspectives on familiar problems. (2007, p. 1)

Anthropology achieves this in different ways. It does this by introducing the possibility of contesting and changing categories (such as gender) by revealing them to be historically and culturally produced, rather than natural (Merry and Coutin 2013, p. 8). This has enabled anthropologists to engage with public issues, in order to counter grand narratives such as the “‘clash of civilizations’ . . . grapple with risky popular misconceptions of culture, difference and suffering and . . . surface less visible forms of compassion, care, and solidarity” (Haugerud 2016, p. 585).

It also does this by raising awareness of alternative perspectives; by attending to the micro level of interpersonal human relationships, anthropology reveals aspects of life that are usually hidden in plain sight. In the process, anthropology also serves to foster empathy and compassion, a cornerstone of which is understanding another person’s perspective (Goleman 2017, p. 4). Consequently, anthropology can also be a driver for such change by contributing to cross-cultural communication and helping build empathy across cultural divides.

Possible in Economics

Béatrice Boulu-Reshef

University of Orléans, Laboratoire d'Economie
d'Orléans, Orléans, France

Abstract

The notion of *possible* has two meaning; first, it denotes the ability to be achieved, second, it denotes the fact that an event or a fact is not certain. Although the notion of *possible* in economics is not literally used in economics, its meaning is absolutely ubiquitous in that the *possible* is an inherent part of the scientific enterprise in economics. The prevalent use of the words the “achievable,” “realization,” “feasibility” for the former meaning and of the “likelihood,” the “probability,” or the “potentiality” for the latter attests of the importance of the *possible* in economics. Inherently, economics tries to predict *possible* states and the evolution of the economy given the variables that it uses. The *possible* is constitutive of the *episteme* of economics as it is central in its main objects of research, that are “value” and “resource allocation,” and in its models and in its empirical methodologies. The *possible* also plays an important role in its three of its core concepts, namely, production, consumption, and trade. The usage of the *possible* in economics is prominent in the dialogue that is installed between theoretical and empirical research, in the studying of the robustness of economic institutions, and the implications of economics type of thinking. In theoretical works, the *possible* is mainly used in the sense of what is *achievable* or *feasible* given the available resources. In empirical works, the use of the *possible* is centered around the search of the explanations that are more *likely* or more *probable*.

Keywords

Possible · Economics · Achievable · Feasible · Likelihood · Episteme · Model · Empirical methodology

Introduction

Etymologically, the notion of *possible* comes from the Latin *possibilis*, which means “that can be done,” which is directly related to the Latin *posse* which means “have power, be able.” The notion of *possible* is also related to the Latin *potentem* (with the nominative *potens*), which means “powerful” and *potis*, which means “powerful, able, capable; possible” and when referring to a person “better, preferable; chief, principal; strongest, foremost.” The proto-Indo-European root *poti-* used in words such as potent, omnipotent, power, or potential, to cite a few, refers to the same idea of “having power,” or being “powerful, able, capable.”

These roots are present in the contemporary views of “possible” that are centered on the ideas that something is *possible* means that is “achievable” and/or “not certain.” Thus, being *possible* has two meanings. First, something is *possible* if it is achievable, i.e., “it can be done or achieved.” In lay conversations, one would use the notion of *possible* to describe conditions that are hoped to be attained, e.g., as in “if possible I would like to get there before noon.” Second, something is *possible* if it is not certain, i.e., “it is conceivable, feasible, plausible, imaginable, thinkable,” and so on. In lay conversations, one would use the notion of *possible* to describe conditions or events that might or might not happen, e.g., as in “that’s the *possible* solution to the problem.”

In economics, the use of the word *possible* is secondary in nature, as often veiled by other, often more sophisticated notions. Yet, although it is not always referred as such, the notion of *possible* is practically ubiquitous in economics. Thus, despite its relative semantic absence, the notion of *possible* in economics unfolds in numerous and important topics of research. This entry will attempt to shed some light on the important accptions of the notion of *possible* in economics.

First, the role of the *possible* in the *episteme* of economics is presented. Light is shed on the importance of the *possible* in the objects of research of economics, on the role of the *possible*

in economic models, and finally on its role in economics methodology. Second, the importance of the *possible* in three of its core notions, i.e., production, consumption, and trade is reported. Last, three usages of the *possible* are provided, to give some insights its role in how scientific advancements come about in economics.

It is important to note that no dictionary entry could *possibly*, even if that may sound ironic, pay homage to the diversity of the various instances in which the *possible* is a constitutive element of scientific advancements in economics as it is used, probably, in all subfields. This entry will attempt to shed some light on the role of the possible in economics, via the provision of an analysis of its role as well as via a few illustrations of its usage.

The Possible in the *Episteme* of Economics

The Possible in the Objects of Research of Economics

Economics studies on individuals and economic agents, in particular groups, firms, or states interact with value and decide on how to allocate resources. This leads to the studying of production, consumption of goods and services, as well as trade or the allocation of goods. Economics applies to many areas of economic life, in particular in the behavior of firms and businesses, in finance, and in government intervention in the economy. Economic analysis is also applied to various areas of social, family, and biological aspects of life, such the study of education, health care, crime, family, real estate, personal finances, politics and administrative life, law and legal system, social institutions, war, the environment, and science. All of the topics relate fundamentally to *the possible* in that they deal with how resources are valued by and allocated among individuals and economic agents.

Dealing with how individuals and economic agents decide over value and the use of resources implies that economics studies primarily the impact of scarcity of resources. This account of scarcity is one of the identity landmarks of economics; the so-labeled dismal science is often

described as the science of scarcity. The resources that are typically conceived as scarce are land, water, labor, health care, roads, utilities, etc. In that, the notion of what is *possible* in economics is conceived in its *episteme* as what is *achievable* in terms of economic output and distribution of income given the scarce resources that are available. The social and economic organizations that make these resources available and their allocation *possible* are the central object of study in economics.

It is important to note that economics expanded its scope by including factors drawn from neighboring fields. For instance, more on the inclusion from psychology can be found in DellaVigna (2009), from neurosciences in Camerer et al. (2005) and from machine learning in Mullainathan and Spiess (2017). Three important examples of these inclusions are the notions of computational abilities (Simon 1955), of capabilities (Sen 1993), and of voice (Banerjee and Somanathan 2001). In those cases, the inclusion of computational abilities draws from computer sciences, cognitive sciences, and psychology, and the inclusion of the notions of capability and voice draws from philosophy, developments studies, and psychology. Inclusions from neighboring fields expand the scope of the *possible* in economics, enriching modeling and empirical abilities of economists. For instance, it adds empirical methods as well as *potential* explanations to economic phenomena that could not be explained by commonly used economic factors.

The Possible in Models in Economics

In economics, models are theoretical constructs representing economic facts and processes using a set of variables and a set of relationships between the selected variables. Economics relies on different types of models, including mathematical models, graphical models, game-theoretical models, econometric models, or even agent-based models. Some are stochastic, in that they include random variables that are central to the functioning of these models. Some are non-stochastic, in that they are quantitative and rely on variables that are qualitative or quantitative

observables. Finally, some are simply qualitative, in that they depict relationships without referring to quantitative measures of these qualitative variables. All economic models rely on the assumption that the variables are relevant and the studied processes are inherently *possible*. Although the distinction between macroeconomic models and microeconomic models is becoming less relevant as microeconomic foundations of macroeconomic phenomena are now commonly investigated, for simply, this entry is organized around macroeconomic models and microeconomic models.

Macroeconomic models deal with the scientific precaution of studying *the possible*, in terms of expanding the potentiality of a model, by including in their analysis what is labeled “model uncertainty.” Model uncertainty refers to the “condition of analysis when the specification of the model of analyzed process is open to doubt” (Onatski 2008). Various approaches are used to represent model uncertainty and they all try to account for the different sources of uncertainty. For example, “evolving model uncertainty” accounts for the fact that the prospective of policy choice affects model uncertainty and the set of *possible* models and relevant parameters should be sensitive to this prospective. Another example is what has been labeled “local model uncertainty” (Onatski 2008) and which consists in building around a model a set of models that are hard to distinguish from the original models; this approach has been used by Hansen and Sargent (2014). These methods for expanding the scientific scopes of models provide some structure for scientific advances as well as policy decisions. Onatski (2008) remarks that one way is to “expand a given model to a more general class and to formulate a subjective prior over this class.” It is important to note that there is no standardized way for representing model uncertainty and that subfields in economics adopt strategies that are specific to their subfield, as shown, e.g., in Berger and Marinacci (2020) for environmental economics. Such efforts provide some guidelines on how to add *possibles* to the sets of explanatory variables and identified processes that may be covered by the model, although not in a most direct fashion.

Microeconomic models, which study the behaviors and interactions of individual economic agents, such as people or firms, account for the *possible* by making risk and uncertainty systematic and fundamental components of the analysis of decision-making. Situations of risk refer to situations in which probabilities are known; for example, insurers know the probabilities of specific accidents, because empirical measures of the frequency of such accidents have been collected for a significant period of time. Decisions in risky environments are typically depicted using the von Neumann–Morgenstern utility theorem (1958). In this workhorse model, an individual or an economic agent who face risky (depicted as probabilistic) outcomes of different choices will behave as if he or she is maximizing the expected value of a function that is defined as the sum of all *possible* prospects, each multiplied with their probabilities associated. The *possible* is described as a sum of *probable* prospects. Situations of uncertainty refer to situations in which probabilities of events are unknown; for example, economic agents know that interest rates can go up, remain stable, or go down, but they cannot assign probabilities to these states of the economy. In fact, risk, with known probabilities, is not treated as a separate case, but as a sub-case of uncertainty, as explained by Wakker (2008), who further states that, “many results from risk naturally extend to uncertainty,” opening the road for explaining why less certainty is in fact less unnatural than more certainty. For instance, the Bayesian approach, based on de Finetti (1931), Ramsey (1931), and Savage (1954), which is a very common way to model uncertainty in economics, relies on the assumption that individuals assign subjective probabilities to uncertain events. As stated by Wakker (2008), “they then evaluate prospects [...] through their (subjective) expected utility [...]” A substantial amount of research is dedicated to the empirical measurement of subjective probabilities. So even when probabilities are not objective in the sense that they are the result of a data collection process on the frequency of the *possible* events, they may exist as theoretical and empirical constructs in economics. Economists find ways to include subjective *possibles*, what individuals

evaluate as likely, when fundamentally these cannot be the results of a fully objective data collection enterprise. This leads us to consider now the role and importance of the notion of the *possible* in empirical methodologies in economics.

The Possible in Empirical Methodologies in Economics

Empirical research methodologies are numerous in economics. Economists use statistical data that they study with econometrics and machine learning techniques, quasi-experimental methods, natural experiments, randomized control, laboratory experiments, surveys, and, more recently, methodologies borrowed from medical sciences, cognitive sciences, and psychology, such as self-declared subjective states, neuroimaging, and physiological measures and from computer sciences with machine-learning techniques. Although they vary in terms of the empirical outputs that they generate, empirical methodologies in economics have much in common, namely, that use probabilistic approaches and that they mostly seek the establishment of causal relationships – although the documentation descriptive statistics of economic phenomena is also central in economics, but secondary in importance. Empirical methodologies in economics relate to the *possible* in that they aim to document the most likely invariant economic relationships, given the current falsifiable analytic apparatuses. This leads to scientific debates. For example, the Philips curve – that has been used to study the relationship between inflation and unemployment – has been an object of research that has evolved since Philips's (1958) initial article, notably because of empirical advances that allowed for better documentation of important factors such as the role of expectations which impact the relationship between inflation and unemployment.

Economists started out their empirical enterprise with a very cautious and ambitious outlook. Frisch illustrates (1933) this early vigilance and aspiration: “At present I am only guessing very roughly at these parameters, but I believe that it will be *possible* by appropriate statistical methods to obtain more exact information about them.”

The notion of the search for improvements in empirical techniques remains structural in economics, and the development of a methodological innovation that extends the knowledge of what is achievable in terms of data collection and empirical analysis is a central aspect of what is conceived as a scientific contribution. Ground-breaking methodological contributions are published in leading economics journals. For instance, the Sveriges Riksbank Prize in Economic Sciences in Memory of Alfred Nobel is also given for methodological contributions, as for example to Vernon L. Smith “for having established laboratory experiments as a tool in empirical economic analysis [...]” or to Trygve Haavelmo “for his clarification of the probability theory foundations of econometrics [...]” In that, empirical methodologies and the resulting empirical outputs are central to the relationship of economics to the *possible* as pushing the limit in terms of what can be *achieved* in terms of scientific abilities.

The Possible in Core Notions of Economics

The Possible in the Notion of Production in Economics

The studying of production in economics can be described as an inquiry into the depiction of what is *possible* in terms of what is *achievable*. Constrained optimization modeling techniques are tools for studying achievable levels of production under constraints. In economics, constrained optimization is done typically using the Lagrange multiplier method and the linear programming method. These mathematical techniques allow to maximize the level of production under a set of constraints that are defined by the scarce resources.

The production-possibility frontier depicts the achievable total output that can be produced by different combinations of input quantities with a given technology and total factor inputs. Each point on the curve shows potential total output for the economy, which is the maximum feasible output of one good, given a feasible output quantity of other goods, as because of scarcity of resources, the use of inputs for one good, takes

away resources available for other goods. At the microeconomic level, the important aspect of production-possibility frontier is that it shows that achieving a certain level of production of a certain good entails an opportunity cost as the opportunity of producing the other good is diminished. Thus, making something *possible* comes at the cost of not allocating available resources to other *possible* economic activities. At the macroeconomic level, the production-possibility frontier allows to show the points at which a region's or a country's economy is most efficiently producing its numerous goods and services. By depicting this highest possible level of production, it illustrates how the region or country may allocate its resources in the most efficient way *possible*. Also, any point within the production-possibility frontier is not "Pareto efficient" – named as such after the Italian economist Vilfredo Pareto – because the total output of commodities is below the *possible* output capacity.

The Possible in the Notion of Consumption in Economics

The studying of consumption fundamentally relies on a similar assumption and theorizing. The act of consumption results from the arbitrage between available quantities of goods or services under the budget constraints individuals or economic agents face. Consumption in economics is about maximizing utility under scarce resources than deciding among alternative goods given their features as a psychological process; much of the core studying in economics is on how prices influence the choice among alternatives given the budget constraint. With respect to consumption, the *possible* is understood as the achievable level of utility, given the budget constraint. Recently, more attention has been given to the impact of what has been labeled the "scarcity mindset" (Mullainathan and Shafir 2013), which refers to the impact of facing financial constraints on the process of making decisions. The "scarcity mindset" is most prevalent among the poor as they lack income, but this mindset may also apply to nonmonetary dimensions of life and therefore affect those who are not poor.

The Possible in the Notion of Trade in Economics
The most essential expression of an economic activity that can be recorded is the occurrence of trade: goods that have been produced are sold and bought to be consumed via an organization of the exchange, which may be done via a market, bargaining or regulated exchanges. Economics offers several theoretical apparatuses and empirical methods for studying trade, and they all relate to the *possible* in that they study the *realization* of the trade between a seller and a buyer. In economics, an Edgeworth box, named after Irish philosopher and economist Francis Ysidro Edgeworth, is a graphical representation of a closed economy with just two commodities and two consumers, and the dimensions of the box representing the total quantities of the two goods. Any *feasible* allocation of the goods between the two consumers is represented as a dot in the box. With respect to the *possible*, the Edgeworth box depicts the *feasible* allocations of the quantities of goods between the two consumers, and although it states that some allocation dominate others – for instance, an allocation that is preferable for one consumer and no worse for the other "Pareto dominates" allocations that do not have these properties – all feasible allocations can be represented and compared and they correspond to *possible* allocations of the goods, although most are neither efficient nor equitable. Another tool that is a central constitutive element of the analysis of trade are the notions of comparative advantage in international trade, developed initially by Ricardo (1817) and largely used in current international trade research (see Costinot and Donaldson 2012, Eaton and Kortum 2012 for recent methodological entries on Ricardo's theory of comparative advantage). With respect to the *possible*, Ricardo's theory states that an economy has a comparative advantage if it has ability to produce a particular good or service at a lower opportunity cost than its trading partners. Thus, if two countries engage in the free market and there are differences in labor productivity between both countries, then each country will increase its overall consumption by exporting the good for which it has a comparative advantage while importing the other good. International trade allows to

increase for each country the *possible* overall consumption.

Usage of the Possible in Economics

The Possible and the Discovery of the Limits of Theoretical Apparatuses: An Example – The Treasures and the Limits of the Nash Equilibrium in Economics

Game theory in economics is widely used to study interactions between individuals and economic agents. The Nash equilibrium, named after John Nash – who received the 1994 Nobel prize together with John Harsanyi and Reinhard Selten for their work on non-cooperative games, states, put simply, that in interactions, each player is assumed to know the equilibrium strategies of the other players and that, if that players choose strategies that lead to a Nash equilibrium, no player has anything to gain by changing only his or her own strategy (Nash 1950). Thus, in games in which the economic incentives are such that no player will gain economically from deviating from the Nash equilibrium, no player should, in theory deviate from the Nash equilibrium. There are situations in which the Nash equilibrium has been documented empirically – as in one-shot games – and situations in which it has not been as validated both with experimental as well as observational data. Goeree and Holt (2001) report laboratory data for games that are played only once, and for each game they document “the treasure is a treatment in which behavior conforms nicely to predictions of the Nash equilibrium or relevant refinement” and “in each case, however, a change in the payoff structure produces a large inconsistency between theoretical predictions and observed behavior.” Empirical validations and deviations of the Nash equilibrium have also been reported for games that are played more than once as well as in natural settings. Goeree and Holt (2001) report that the documented “contradictions are generally consistent with simple intuition based on the interaction of payoff asymmetries and noisy introspection about others’ decisions.” Several other *possible* explanations for the deviations have been documented in economics; this scientific inquiry into the

discovery of the *potential* factors that may, under certain conditions, falsify this theoretical apparatus is an illustration of how economics uses the *possible* in the dialogue that is organized between theoretical and empirical research.

The Possible and the Proof of the Existence of Mechanisms: An Example – The Robustness of Market Equilibrium and the Existence of Alternative Market Mechanisms in Economics

The notion of market equilibrium describes situations in which demand and supply forces are balanced, the situations in which they equilibrate. Supply and demand meet at a point in which the equilibrium price leads to no surplus, in the sense that the quantity supplied is no greater than the quantity demanded, and it also leads to no shortage, in the sense that the quantity supplied is no less than the quantity demanded. At this price, the suppliers do not have excess inventory as the price is low enough so that buyers could buy and they do not face shortage of inventory as the price is high enough so that the quantity that sells is lower than the quantity that would have sold at had the price been lower. Although quite intuitive, this market equilibrium mechanism remained at least partially a hypothesis until proven in experimental settings. As Vernon Smith (2002) puts it in his Nobel biographical essay: “To my amazement the experimental market converged ‘quickly’ to near the predicted equilibrium price and exchange volume, although there were ‘only’ 22 buyers and sellers, none of whom had any information on supply and demand except their own private cost or value.” The convergence of experimental market when buyers and sellers do not have any information about the market equilibrium but only individual values and costs proved that information diffusion is made *possible* by the experimental market institution in that the several trading periods allowed the traders to obtain experience, information about the clearing prices and to adapt over time. This so-called “ecological rationality” is one of the more advanced scientific expression of what Hayek (1945) had stated when defending that the sum of knowledge held by all members of society is greater than the knowledge held by individuals as knowledge spread throughout society.

The Possible and the Implications of Economics Type of Thinking: An Example – The Notion of General Equilibrium in Economics

The notion of general equilibrium, which was initially developed by Leon Walras (1874) in the late nineteenth century, accounts, in its simplest form, for how supply and demand interact and tend toward a balance in an economy of multiple markets working at once. This balancing leads ultimately to a price equilibrium, which accounts for competing levels of supply and demand in different markets. Although not all of economics is done in general equilibrium setting in that analysis is done in one market – such analysis is labeled “partial equilibrium analysis” – the fact that economists are cognizant of general equilibrium has an impact on how research is conducted and how the *possible* is conceived. For instance, the pervasive use of probabilistic approach is to be conceived as a cautious measure to account for the fact that *ceteris paribus* analysis may not account for the general equilibrium “adjustments,” which describe the fact that what happens in a market may impact other markets of the economy and, in turn, re-impact the initially estimated variables. For example, the increase in take-up in professional training in a given region may increase overall employment, and thus generate demand for goods and services in sectors of the economy that were not the object of the analysis initially, that in turn raise further the demand for education and, *possibly*, the overall take-up in professional training. The initial empirical estimates did not account for these general equilibrium effects but the use of probabilistic approach provide a cautious measure of how parameters evolve given the limited number variables that are taken into account in a given analysis.

Conclusion

The use of the *possible* in economics is mainly determined by whether the *possible* is used for theoretical or for empirical research. Theoretical research in economics relies primarily on a notion of the *possible* that describes what is achievable or

feasible given the available resources. Empirical research in economics relies primarily on a notion of the *possible* that describes what is likely or probable in terms of explanations for the economic phenomena observed.

Possible in Education

M. S. Neves-Pereira

Universidade de Brasília – UnB, Brasília-DF, Brazil

Abstract

Education is a masterful word. Masterful comes from master, mastery, skills, virtuosity, expertise, teaching, and learning, making something possible. There is no one single social group whose members do not educate each other. Regardless of the level of development of a society, all its members are educated throughout their life cycle. Education may come through formal means, through schools, universities, religious education, and other institutions, or during daily experiences in the confrontation of day-to-day life, which demands multiple learning. To talk about education is to talk about our history, to think about the long life path in which we are subjects of a culture together with each other, in social interactions. To speak of education is to think of possibilities and to think of possibilities places us before limits, barriers, impossibilities. The word Education comes from the Latin verb *educare* that unfolds into two different meanings: *ducere*, which means to take, guide, lead someone somewhere, and *educare*, which is linked to the sense of nurturing, raising (a child), and making

(someone) grow. In this entry, we will talk about education in its formal dimension: one that involves human development processes, that generates the new, that demands teaching, that generates learning, and that requires creativity. We will discuss these processes in the light of the philosophy of education, cultural psychology, and the psychology of creativity, seeking to understand how educational acts transform human beings, (re)signifying their existential experiences and changing the world in which we live. Possibilities and impossibilities will be problematized throughout this discussion.

Keywords

Education · Possibilities · Human development · Creativity

Education Is the Land of the Possible

Education is the Land of the Possible. It is the praxis that constitutes our humanity, our condition as bodies conscious of themselves, the other, and the world. It is through education that we take hold of the legacy of our species. It is the indispensable condition for the construction of the historicity of man. When human beings educate one another, they push the wheel of development of our species. Educating has to do with leading and mediating others in the face of the challenge of existence. To survive we need to learn whom we are, how the world around us works, we need to develop psychological functions, master language, and our mother tongue, and we need to build beliefs, values, and views of the world. Freire (2013) already said that “nobody educates anybody nor does anybody educate themselves; men educate one another, mediated by the world” (p. 1247). In this entry, we will look at formal education, the one offered intentionally in institutions. We will use the pedagogical and psychological discourses of different authors as a resource for analysis to reflect on the dimension of the “possible” in the human educational and developmental experience, processes that are potentiated by teaching. When we arrive at the school, we

bring a huge baggage of knowledge that will be confronted with the knowledge historically constructed by humanity, immersed in the school contexts; we concomitantly start to become subjects of knowledge and subjects of culture (Vygotsky 1991). Our human potentialities and possibilities will arise; values, beliefs, and views of the world will be constructed through the dimension of identity that we understand as subjectivity, self, as the view we build of ourselves, and that is transformed throughout the life cycle. Development processes have specific marks, characteristics, and dynamics. These processes include the gestation of the new and the presence of creativity in its multiple aspects (Valsiner 2014). Educational acts transform human beings, (re)signifying their existential experiences and changing the world in which we live. Educational acts promote human development. Human development is a creative process and therefore opens to all dimensions of the possible. We return to school as the Land of the Possible, where our species dwells and lives. At this point, a question arises: how to make real what is possible from educational practices, since the impossible is part of the very process?

Possibilities in Education: The Ways to Think About This Relationship

Thinking of education as a space that creates possibilities requires from any author consistent epistemological and theoretical positions capable of providing elements that allow an appropriate analysis of the theme. In this entry, we will problematize the pedagogical practices starting from plural theoretical positions that have been dialoguing during the last decades as a consequence of their ontological and ontogenetic vocations. We will explore Paulo Freire's work (Freire 2013, 2015, 2017) and the contributions of Bruner (Bruner 1990; Marsico 2015; Takaya 2013), two great theorists who have placed education and psychology as fields of possibilities in mediating processes of human awareness and humanization. Freire and Bruner interconnect the fields of psychology and education based on

unique existential experiences – the former lived the vicissitudes of being a Brazilian educator persecuted and exiled by a disastrous military regime and the latter was born in the USA, experiencing, in theory, a full and consolidated democracy. Their interconnections allow us to look into the educational phenomenon as a context for the construction of possibilities, as a phenomenon born in the collective, in cooperation, in the alterity that makes us see and perceive others, in the processes of awareness of the subjects, their humanity, their right to education as a means of achieving a dignified and fair existence. By integrating the human developmental dimension into the discourse of liberating and promoter pedagogies of the possible, we will use the cultural psychology (Valsiner 2014, 2019), a theoretical model that deepens the understanding of the subject in joint-construction of himself, in relationships of alterity and immersed in different socio-cultural contexts, including schools. Finally, the cultural psychology of creativity (Glăveanu 2014, 2015; Glăveanu and Neves-Pereira 2020) closes this discussion by highlighting the act of creating as an action that connects the real, the imaginary, and the possible as praxis of human liberation, as an experience shared by all social groups, in different forms, ways, powers, and possibilities and, arguably, linked to educational and developmental processes. The act of creating inserts us into the world of the possible, and therefore cannot be seen as an action detached from becoming the subject of culture and learning.

Paulo Freire's Educational Practices and the Universe of Possibilities

Educators generally regard education as a promoter of possibilities. It sounds quite obvious that education opens doors and broadens human paths. This scenario would be perfect if real existence was not harshly positioned before this dynamic, turning practices that generate the possible into acts, sometimes little promising (Freire 2013; Fourez 2006). In different countries, public policies, pedagogical projects, and teaching plans

emphasize ambitious and humanitarian educational objectives, always aiming at the comprehensive training of the human being, the mastery of the literate culture, the development of literacy and the insertion of the subjects in the world of the written language, the training and development of logical-mathematical reasoning, the construction of knowledge in the human and natural sciences, among many other purposes that launch the children, qualitatively and quantitatively, in a world far beyond what they supposedly knew before entering school. Being formally educated, attending a school is a phenomenon that definitely changes subjects, not always towards the noble educational goals. A quick analysis of the purposes of formal education systems in the most diverse socio-cultural contexts leaves no doubt that education arises as a redemption of the human being, as an action that will insert subjects into the literate culture, which will enhance their cognitive and creative capacities, and many times education is perceived as the only possibility of development of a nation. Educating is an action that promotes changes, individual, collective, and social transformations. However, the school is not always a space capable of leading to new possibilities, in many ways. The school, we must not forget, is a social institution at the service of the State, the society, power groups, and tends to reproduce their explicit and implicit norms, rules, values, and principles (Fourez 2006).

Paulo Freire's critical and politicized pedagogy (2011, 2013, 2015, 2017) puts a hand on this wound. Freire speaks of school at the service of the ruling power, of teaching as an instrument of human oppression in an objective, direct, and courageous manner. His model consists of a theoretical approach that plunges into education as a context of (many) possibilities, but invaded by impossibilities created in the dominant socio-cultural and political spaces in capitalist societies. To educate, in the view of Freire (2011), is to recognize the subject whose body was politically interdicted by his/her oppressors and, therefore, not recognized in his/her humanity. He highlights the dynamics experienced by this subject to whom the educational and existential experience was denied: the subject of a body that can only be educated with

his/her peers and at the moment when he/she becomes aware, that he needs to free himself/herself from oppression and become an agent of change (Freire 2013). Freire discredits the regular education systems that often treat teaching as a banking transaction, where teachers (the possessors of knowledge) deposit the knowledge in the minds of the students (the receivers of knowledge and devoid of it) who can later draw these knowledge and transact it in life for money, work, or position. This view of education disqualifies the subject as an agent and protagonist of the construction of knowledge, making the learning process dissociated from life and its socio-cultural, economic, and political implications (Freire 2013, 2015). The oppressed one is educated to reproduce the social and political system in which he lives and, since this education does not emancipate him, endowing him with administration and freedom of action, the student ends up reproducing the system of oppression that imprisons him/her. To be a generator of possibilities, pedagogy has to be liberating, problematizing, and a raiser of awareness in the full expression of these concepts. It has to be a sort of pedagogy of "the" oppressed one and not "for" the oppressed, because only the oppressed one can break free. The oppressor does not free anyone because he/she cannot afford to do so. Freire (2013) is radical when he says:

The practice of freedom is incompatible with a pedagogy that, consciously or mystified, has been a practice of domination. The practice of freedom will find adequate expression only in a pedagogy in which the oppressed can reflexively discover and conquer himself/herself as subject of his/her own historical destination. (p. 57)

What are the possibilities of education in the face of a radical pedagogy like Freire's? What are the paths that allow the liberation of the oppressed ones, who constitute the majority in the human species, in the face of the oppressors? What to do when faced with the possibility-killing reality of the school? As highlighted by Brighente (2016):

(...) therefore, a worldview that denies and forbids men and women ends up being reproduced and legitimated by the school. When educators deny that their learners are subjects, they "fabricate" objects to create the homogeneous and standardized mass of the capitalist mode of production, to

produce and reproduce the rules and culture imposed by the dominant individuals, maintaining the *status quo*. (p. 159)

Pedagogical models that understand education as social and political processes engendered in social interactions and contaminated by all the values, beliefs, laws, and desires of men who dominate groups, social systems, and nations, and know that there is no naivety in this cause (Dale and Hyslop-Margison 2011; Freire 2013, 2015; Fourez 2006; Giatti and Murzyn-Kupisz 2019). To educate a human being means to endow him with some kind of power, even if it is the power to know how his name is written. This little piece of knowledge can revolutionize lives. The fact that education is a carrier and promoter of “so many” possibilities makes it a critical area that lives under the eyes of power. How to deal with so many limits, impediments, and restrictions and, despite the owners of the world (Chomsky 2016), make education a democratic gate to human possibilities?

Jerome Bruner's Educational Practices and the Universe of Possibilities

Psychology has made important contributions to pedagogical discussions by placing human development and learning as interdependent and co-constituting processes of human psychological functions. Bruner (1990, 1996; Marsico 2015, 2017; Takaya 2013) is one of the authors who understand education as the core of the process of becoming human. In his work, he stresses education in a very significant way, seeking not only articulations between the psychology he practiced and educational processes, but also stating his position as an author committed to the education of his country. In his 100 years of life, Bruner devoted much of his time to educational studies, investigating the importance of education for the construction of psychological processes (Marsico 2017), the relevance of the curriculum for formal education, the intricacies of teaching science in schools, and how teaching methods should address school content (Leme 2011). His studies on cognition, perception, and the processes of

significations (this last theme was motivated by his work relationship with Luria in the 1950s) led him to question aspects present in the learning processes based on his knowledge of psychology.

Bruner's questions were not the same as Paulo Freire's with his politicized pedagogy. Bruner did not embrace the political dimension of education but rather its psychological dimension. His questions arise from theoretical models practiced in the United States in the twentieth century, and his forays into other cultures, including Vygotsky's and Luria's Russia. His contributions come from the dialogues and bridges he built between psychology and education, signaling a world of possibilities present in the processes of human development, learning, and especially in the act of teaching (Leme 2011; Marsico 2017). In summary, we can call Bruner's psychology as constructivist, oriented to ontogenesis and considering semiotic processes as mediators of human development, managed by a subject that is circumscribed to time, which is irreversible (Marsico 2017). As the author points out:

Human agents doing things on the basis of their beliefs and desires, striving for goals, meeting obstacles which they best or which best-them, all of this extended over time. It is narrative in nature, that has 'inherent sequentially' or plot. This feature determines 'the mode of mental organization in terms of which it is grasped'. (Bruner 1990, p. 44)

The subject who builds himself through complex developmental processes, immersed in different shaping sociocultural contexts of these processes and still counting on typical biological limitations of our species, is yet able to overcome his limitations, to go beyond his own history, imagining and creating, build new worlds, ideas, and works (Glaveanu and Neves-Pereira 2020; Neves-Pereira and Silva 2019; Valsiner 2014). For Bruner (1996), man is able to unite these poles: the real and the imaginary, the current and the possible. Man is a being of possibilities, dealing with constraints, social rules, norms, and laws, but capable of breaking with his own history, giving rise to the new. Bruner sees man positioning himself, ontologically, between the possibilities and interdictions present in the sociocultural and political contexts, facing and resignifying these interdictions through

his ability to imagine and create the impossible. Marsico (2017) highlights:

Cultivating the sense of what is possible in our educational practices well represents the Brunerian constructivist vision of the human being as a future-oriented agent who strives to overcome the borders of actual reality towards new possible worlds. (p. 11)

Bruner (1996) reinforces the ontological vocation of the human species to overcome limits, by imagining and creating possibilities in multiple contexts. Man's perceptive and symbolic capacity throws him far beyond existential barriers and limitations, allowing for creative, disruptive learning that articulates and surpasses the real, the imaginary, and the possible. Bruner was a visionary, betting on the ability of new generations to develop their creative potential, to imagine new scenarios for the world and build them (Marsico 2017).

Bruner's legacy to education is very well expressed in Marsico's (2017) speech, which highlights:

Cultivating the meaning of what is possible in our educational practices represents well the Brunerian constructivist view of the human being as a future-oriented agent who strives to push the boundaries of current reality toward new possible worlds. (p. 763)

The Pedagogy of the Possible: The Real, the Imaginary, and the Creation

An education that considers the relevance of psychological processes in development, with their constitutive dynamics, and that understands how the subject learns and builds his/her view of himself/herself and of the world (Valsiner 2014) is able to promote the Freirean praxis (Freire 2013), that is, it is able to embrace a pedagogy that mediates the subject in the act of reflection that inserts him in his own history and in the world, transforming his reality, constructing his humanity. By articulating teaching and life, imagination and creativity, this pedagogy promotes the possible. This "possible" is not an innocent or naive phenomenon, but an existential condition that perceives itself dealing with the limits of the lived experience, with socio-cultural barriers, facing the absence of autonomy, which is taken away

from subjects by norms and rules and returning power, knowledge, and capacity of action to the agent. It is in the perception of the limitations imposed on the possible, in the efforts of the oppressors to institutionalize the "impossible" that the power for the new arises. There are cracks in these gears that allow barriers to break down and creativity to flourish, to awaken a world of possibilities. Despite the oppression, impossibilities, and interests of powerful individuals, the power of education is unstoppable because it inhabits cracks, hiding places, subtexts, and other real and symbolic contexts that characterize the spaces of resistance.

Bruner (Marsico 2017) used to say that life always includes a dialectical clash between limitations and possibilities and that perhaps the way out of this clash was situated at the boundaries between possibilities and impediments throughout the human developmental processes. Cultural psychology also proposes a perspective of man in innovative development, creating theoretical and methodological possibilities to investigate, analyze, and theorize about development processes from a different perspective, open to the new and to the possible. Discontent with what is "established" has been moving psychology theorists to transform scenarios and propose more creative views about man building himself and the world in a two-way, co-constituted, and profoundly creative manner (Glaveanu and Neves-Pereira 2020; Valsiner 2014).

In almost every school, where social, political, economic, ideological, and pedagogical interference take place, children struggle with meeting school demands and/or building a sense of belonging in relation to themselves, to knowledge, to the school itself, and to the world. How can one imagine, in multitone contexts, the development of creativity, for example? Research about processes of development of creativity at school (Neves-Pereira and Branco 2015; Neves-Pereira and Silva 2019) has repeatedly shown how values, beliefs, pedagogical models, interferences of pedagogical, administrative, and political management prevent that creativity, as a human resource, flourish in schools so as to benefit the entire academic community. These unpromising scenarios, however, are also inhabited by real possibilities that open

the way for imagination and creativity to point out possible paths. The social and collaborative nature of creativity, its symbolic dimension, and its developmental perspective (Glăveanu and Neves-Pereira 2020) place it in the fertile ground of possibilities. If education is the Land of the Possible, as stated at the beginning of this text, creativity organizes the arena where possibilities emerge as acts, works, productions, and intentions of subjects. These possibilities take shape, transforming minds, lives, changing the world, promoting autonomy, and rehearsing freedom and human empowerment. Creativity is the human resource that integrates the real, the imaginary, and the possible in the form of creation. As an exclusively human action, creative expression and action become indispensable for any educational system to in fact achieve humanizing goals.

Conclusion

Embracing the crisis that arises when one disagrees with the zeitgeist is essential for the development of science. Fourez (2003) explains that the word “crisis” has an interesting definition in the Chinese dictionary: it is formed by two ideograms with different meanings. The first ideogram means “danger” and the second “possibility or opportunity.” It is the second ideogram that will inspire the final reflections on education and its power to generate human possibilities. The authors discussed in this entry made a critical analysis of educational and psychological scenarios through different theoretical, social, and political paths. Besides problematizing the real experience of the subjects in educational contexts, they also considered paths that can be built to promote a successful school experience, so as to open the gate of possibilities (if not for everyone, at least for some), so that human and cultural renewal may take place in the history of mankind.

Paulo Freire (2013) points to the force present in the act of teaching, to the power existing in the teacher and in the students who, together, are able to mediate cognitive processes among them. As critical investigators, students and

teachers look at reality, recreating it, bringing out the new in various ways, such as: the autonomy that comes from the act of teaching and learning, the construction of oneself as a subject inserted in the world. This subject born of this pedagogy, which is also autonomy (Freire 2011), is an actor and author of his/her history despite the social, historical, and political limits that must be faced, investigated, and overcome in multiple ways. Bruner (1996) insists on the power that resides in beings capable of signifying their worlds in the most diverse ways, in subjects who develop, learn, and teach creatively and innovatively, in the human possibilities they find in schools, scenarios to develop. Cultural psychologists (Glăveanu 2014, 2015; Valsiner 2014) bring the breath of creativity not only as an object of study and theorization, but especially as a human resource that is unquestionably present in our species, perhaps the only resource that allows the effective realization of what once was a mere possibility.

Creativity is inscribed in the human experience as the road to the Land of the Possible. Only the subject, agent of himself/herself and of his/her creativity, is capable of building possibilities. In his/her developmental path, immersed in cultural contexts and close to others, this subject can transform lives, change the world, reconstruct cultural meanings, and even destroy everything we know as existence. Education is the tool we have historically invented to mediate the human power to create. May we use this energy wisely, ethically, and with humanity. Certainly, the possible will emerge out of creativity.

Possible in Human Development

Ramiro Tau

Faculty of Psychology and Educational Sciences, Université de Genève, Genève, Switzerland

Abstract

The notion of “human development” is used polysemically in everyday language, it is present in popular media, political discourse, and several different branches of the sciences, and these iterations often contain ambiguities that are the result of non-specific notion of “development”. In very broad terms, “development” usually refers to the progressive series of changes in a behavior, a function or a structure throughout the life of a person, an organism or a society. Within this series of changes, “the possible” is often characterized as the constantly evolving spectrum of future scenarios, usually in the form of an unachieved but pre-figured stage or phase, or as the opening toward essentially unpredictable transformations. In any case, it is possible to recognize in this diversity a series of common, although generally diffuse, ideas: change over time, evolution, growth, transformation, increase of certain magnitudes, and the passage from a potential and latent state to a current and expressed one. When the notion of development refers explicitly to the human, it can suggest changes in phenomena as wide-ranging as those concerning the biological body, and the mind of the individual to the political and economic macro-processes that take place in large societies. However, the notion of “human development” is most often used as a syncretic category, bringing together in a holistic way all these biological, psychological, or social dimensions. In these cases, it is often confused with some form of evolution, both in its teleological versions or in those that do not recognize a pre-designed directionality, even if they attempt to explain or describe changes over time. These different conceptions

of human development are always supported by a corpus of metatheoretical assumptions. In particular, those commitments that refer to the recognized entities, the nature of changes, and the reasons for their occurrence.

Keywords

Human development · Transformation · Change · Variation · Possible · Time

Within the scientific context, “human development” is a polysemic notion, which takes on highly variable meanings in different scientific traditions and fields of reference (Lerner et al., 2015). In some cases, it refers to changes that can be identified throughout a persons’ life, as primarily endogenous or internally driven processes. Other perspectives emphasize the socio-material conditions that enable the expansion of human capabilities (Ul Haq, 1995). In the latter sense, human development is the direct or indirect effect of the context on the subject. Beyond these two schematic and opposing positions, all definitions of human development attempt to coordinate these two poles, in different ways and with variable success, in order to explain or at least describe changes over time. Whether emphasizing context or internal processes, some kind of necessary relationship between individuals and the world is accepted to a greater or lesser extent (Valsiner, 2000). In other words, the explanation of change requires the recognition of complex interactions between factors at multiple levels. However, this broad agreement on the principle of interaction between the social and the individual is less pronounced than the disagreements that manifest when it comes to explaining concrete phenomena (Lerner, 2012; Overton, 2015; Overton & Müller, 2003). Each discipline and theoretical tradition proposes its own models of change in the human domain, with different perspectives on what change means and why and how change happens (Lerner, 2018; Overton & Müller, 2003). This is not as a result of limited conceptual unification efforts, but rather as an inevitable consequence of the different epistemic frameworks involved (Castorina, 2021). Indeed, economic

theories are predominantly interested in the social and material conditions that facilitate or restrict certain human capabilities. Something similar occurs in the field of biological sciences, which are much more focused on the physicochemical interactions between an organism and its environment. For their part, psychology, epistemology, philosophy, linguistics and other sciences interested in the production of meanings put the accent on the processes that give rise to or shape the semiosis that guides actions. The existence of these fields of specificity does not imply to deny the simultaneous intervention of multiple levels in the developmental phenomena under consideration, but not all dimensions are pertinent or significant for the explanation or modelling of phenomena of a different nature.

Developmental Change

To understand conceptual variability in the study of human development, it is first necessary to consider the general notion of development. Although it is usually adjectivized, its generic use designates the progressive series of changes in a behavior, function, or structure, something that occurs in a person, a living organism, or in human institutions – culture, economy, family, normative systems, etc. In almost all cases, it is an idea often confused with the notion of evolution, with continuist connotations (Doron & Parot, 1993; VandenBos, 2007). In other words, it is assumed that development is a passage from one moment, stage, phase, or level to another quantitatively or qualitatively different one, which maintains some link with the preceding one. In this transition, the later moment is usually recognized as more stable or complex than the preceding ones, with the previous ones being its necessary condition. In other words, a current form or content rests on previous ones without which it would not exist (Foucault, 1957). Occasionally, development is associated with some variety of finalism or teleology: changes have a direction or even a purpose (Rosenblueth et al., 1943). This idea about the direction that the changes follow, although criticized in biology and other sciences

(Wagner-Egger et al., 2018), today takes on a new meaning for cybernetics and artificial intelligence, domains in which artificial systems evolve and self-generate according to a set of goals defined from their initial construction (Contreras-Koterbay, 2019; Kamath & Liu, 2021). On the contrary, there are conceptions of development that do not appeal to a finalism, but to a certain efficiency, as in Darwin's theory of evolution (1859). In these conceptions, changes in the structure and function of organisms are random, being adaptation to the environment the basis of selection, orientation, and fixation of transformations. Following these theses, contrary to any preformism that considers the final stages as the manifestation of what was already latently anticipated (Van Geert, 2003), studies on phylogenesis greatly expanded theories on development (Futuyma, 2017). The detailed exploration of the combination of genetic mutations and the adaptation that results from the somatic expression of these genes consolidated the study of the dynamics between organism and context. Thus, while recognizing the zygote as the key point in the development of a biological organism, the changes that will occur in its development are unpredictable at some scales and predictable at larger ones – for example, we know with certainty that it will die. This difficulty in predicting at all levels is not due to a lack of information – operational chance, in Monod's (1970) terms – but to the essential chance that regulates the processes of open and complex systems (Chapman, 1988; García, 2006; Overton, 2006). The initial genetic conditions do not determine the subsequent course of development, but the field of possible orientations. Even though this makes it impossible to predict development, the transformations that actually occur can be reconstructed retroactively, and explained as the result of the complex and incessant interactions between the organism's dispositions and the conditions of the environment (Waddington, 1957; Valsiner & Connolly, 2003).

Following Overton & Müller (2003), it is possible to recognize some basic conceptions of change in different theories on development. On the one hand, “transformational” change is the

one that gives rise to the emergence of novelties. It is a change that produces something qualitatively new, which was not announced in the previous forms or organizations and, consequently, implies a discontinuity. This transformational change leads to increasingly complex forms and involves a dialectical relationship between continuities and discontinuities (Overton & Reese, 1981), since it is not a creation *ex nihilo*, but neither is it reducible to the preceding organizations. “Variational” change, on the other hand, is a modification of a predominantly continuous and quantitative nature. Strictly speaking, it refers to a change in the degree or scope of a function or capacity, as in the acquisition of a new lexicon or the inclusion of new beneficiaries in a legal system that remains essentially unchanged.

At least three metatheoretical solutions can be identified from these two modes of change: it is possible to emphasize one or the other, or to assume the complementary participation of both. In the first case, development can be conceived essentially as the result of a variational change. Thus, qualitative changes are the phenomenal appearance of the accumulation of variations. This solution disregards transformations and reduces them to linear, summative processes. The second solution, on the contrary, characterizes development as an essentially transformational process of qualitatively different steps, in which variations are irrelevant. Finally, in a relational model, variation and transformation can be a necessary part of a theory of development, since it is assumed that variations can result in transformations, and transformations can lead to variations (Overton & Müller, 2003).

The adoption of any of these three perspectives on development has methodological and theoretical consequences (Valsiner, 2006). The strategies for data production and analysis to study development will necessarily be different if one of these changes is considered predominant or if they are recognized as coexisting. In terms of theoretical implications, the variational approach presupposes systems of linear changes, in which unpredictability is lower. It was precisely this summative approach of American behaviorism that led Watson (1958) to make one of the most famous and enthusiastic claims in the history of

psychology: that through training and conditioning it is possible to shape the future of a healthy child, making him, for example, an artist, a doctor, or a criminal. Transformational perspectives on development, on the other hand, often fail to explain the occurrence of the observed changes. If the change results in ruptures or in moments radically different one from the other, it is difficult to see any kind of common process in such a series, which puts into question the very idea of development as a process. Unless an invariable sequence is admitted in such a model – which, in turn, renders useless any effort to modify a future confused with destiny – transformations can neither be provoked nor predicted. However, the broad spectrum of relational explanations, in which transformation and variation are dialectically coordinated, expands the field of the possible. These explanations open up a potential zone that is not reached in a chaotic manner, but also does not follow a pre-designed path. From this standpoint, development can follow completely different directions and still show a progression in which the coexistence of continuities and discontinuities can be recognized (Chapman, 1988).

The Problem of Time in Human Development

Any theory concerning development, whether explicitly stated in its research agenda or not, presupposes a particular conception of time (Lenzi et al., 2010). Nevertheless, not every theory that considers a temporal dimension implies a theory of development. In fact, not just any change or modification across time is development. In other terms, a diachronic perspective of a phenomenon is not sufficient to inscribe a theory in the field of development. On the contrary, if we assume that in development there is a dialectic between variation and transformation, the decisive aspect is the emergence of novelties, starting from previous systems or structures that do not contain them (Overton & Müller, 2003; Valsiner, 1998, 2006; among others).

Conceptions of time are often expressed in the visual form of lines, arrows, trees, or surfaces, which account for trajectories, divergences, turning points, loops, inversions, etc. (Yamada & Kato, 2006). All of these spatial representations of time are often unidimensional (Rudolph, 2006), and they often have vast implications for the modelling of theory, or at the very least expose the underlying assumptions of the researchers. Although mathematicians have developed complex structures that could be used to represent the complexities of developmental time, the social and human sciences have either ignored these discoveries or simply fallen back repeatedly on some version of physics' "clock time" (Rudolph, 2006). Indeed, even if "irreversibility of time" is accepted as an axiom in theories of human development, this claim may be insufficient or inaccurate, depending on the system and scale under consideration. Psychoanalysis, for example, has shown that, with regard to the effectiveness of certain representations for the production of symptoms, timelessness must be admitted for the unconscious system of the psyche. Something equivalent happens with retroaction, or the capacity to give new meaning to the past from the present or from some anticipation of the future (Arlow, 1986). With other objectives, Piagetian genetic psychology showed that memory is reconstructive and that the progress in the child's cognitive organization affects the mnemonic marks from the past, modifying the memory of the same event evoked at different times (Inhelder, 1970). In any of these cases, the representation of time as a line, or even with loops and inflections, is limited and poor in relation to the complexity of the temporal processes involved in these developments.

The representation of developmental time does not simply refer to the use of graphic structures, but to the very configuration of the theoretical model. Consequently, the field of the possible is expanded or contracted according to the way in which time is modeled in development. In exclusively linear models, the possible is confused with the future, since it refers to what has not yet happened, regardless of whether the projection is determinate or indeterminate. In complex models,

involving retroactions, overlaps, or different dimensions, the possible may also refer to the present and the past, which is counter-intuitive, but particularly evident in different models of cognitive or psycholinguistic development.

Human Development and Socio-material Conditions

The polysemy of the notion of “human development” to which we have already referred, reproduces in the field of development the multiplicity of the human and the problems of its definition. All the classical categories used to characterize what distinguishes humanity from nature reappear when we coconceptualize development: nature-nature, continuity-discontinuity, stability-instability, subject-others-world, etc. Although there is tacit agreement on the multidimensionality of human development, some authors began to criticize, from the beginning of this century, the vagueness or partiality of some formulations. Thus, for example, after defining human development as “human flourishing in its fullest sense-in matters public and private, economic and social and political and spiritual”, Alkire (2002) critically points out that “if human development is ‘multidimensional’ then perhaps we need to discuss what is a dimension, and what are the multiple dimensions of interest” (p. 181).

To address this, much of the literature on human development is concerned with the growth of the human organism, as well as with affective or cognitive changes of a period of life or of life as a whole – the *life-span* perspectives. Other traditions have been interested in the socio-material factors of development. Since the 1990s, the United Nations Development Programme (UNDP) has been promoting a specific paradigm for studying, promoting, and measuring human development. According to this international organization, human development is “the process of enlarging people’s choices by expanding human functioning’s and capabilities” (UNDP, 2000, p. 17). In this framework, the focus is explicitly on Man and the creation of life

opportunities, although, comparatively speaking, contextual aspects are much more relevant than in other research traditions. In fact, the Human Development Index (HDI), a statistical indicator derived from this paradigm, “measures the average achievements in a country in three basic dimensions of human development—a long and healthy life, knowledge and a decent standard of living” (p. 17). Through this index, countries – not individuals or regional populations – are ranked on the basis of life expectancy, access to education, and per capita income—associated with no further consideration of the notion of “quality of life”.

The HDI is an instrument that aims to identify the field of present and future possibilities for human development. That is, to determine objectively whether people are in a position to “be” and to “do” in the course of their lives. From this angle, human development is a field of possibilities that is amplified when certain socio-economic conditions are achieved, with the freedom of individuals being one of the fundamental pillars.

Convergence Frameworks in Human Development

Since the twenty-first century, what is known as the “convergence explanatory framework” or “developmental science” has become more firmly established. This perspective, based on complex systems theory, aims to establish the general principles of human development, regardless of the type of phenomena considered (Lenzi et al., 2010). This relational systemic approach (Lerner et al., 2015) – based on a relational metatheory and on the dynamic relationship between individuals and contexts – configures a field informed by science, but also by philosophical, methodological, and epistemological reflection. The main challenge of a unified model of human development is to avoid the different reductionisms into which disciplinary models lead. This implies linking the level of an embodied agency with that of its different levels of contextual

integration. This discipline draws on different considerations of change as it is studied and explained in human studies, but also in natural disciplines, as well as in the models offered by the formal sciences.

In discussing general theories of development based on complex systems, it is necessary to mention the critique to classical causal explanation (Castorina & Baquero, 2005; García, 1999), because of its inadequacy in producing consistent complex explanations of change over time. Classical causalism establishes injective relations between causes and effects – for an event ‘a’ to be the cause of an event ‘b,’ three conditions must be met: that ‘a’ happens before ‘b,’ that whenever ‘a’ happens ‘b’ happens, and that ‘a’ and ‘b’ are proximal in time and space (Ferrater Mora, 1965). Current models of change, and especially the interrelationship between variation and transformation, cannot be captured if change is reduced to a succession of causes in the classical sense (Overton & Müller, 2003; Valsiner, 1998). Instead of exploring the underlying causes of observable changes in human development, a convergence approach attempts to explain the emergence of novelty through self-organization, as well as the exploration of the courses, disturbances, transformations, interactions, and reorganizations of a complex system.

The Possible, the Impossible, and the Necessary in Human Development

If we accept that development implies the emergence of a novelty that is not prefigured, development can only be judged retroactively, by reference to an instance in the past (Chapman, 1988). In the case of the development of social institutions or the conditions for the expansion of human capabilities, the anticipation of a direction for development is no more than an ideological imposition. In open systems, the direction that development will take is essentially unknown, as we have pointed out. This condition of complex systems will modify the possible futures, but also, at each moment, the way of conceiving the present

and of interpreting the past in its meaningful relations with current facts. In this sense, human development must be considered as a process of opening up possibilities. And in this process, the boundary conditions exert a certain action, but they do not define the perimeter of what is thinkable or achievable. As Piaget (1981) showed, the formation of possibles is a strong argument against empiricism, since possibles are not “observable” – that is, ascertained in facts – but the result of the action of subjects. If the possible is not the result of the “reading” of facts, but of the interaction of subjects with the symbolic and material world, the possible is essentially creation, invention. And this implies two symmetrical aspects: constraints and needs.

Does the idea of progress – or development – work in a multidirectional and non-teleological model? In other words, is there a way to recognize levels of progression in non-linear models? This is a key question in human development studies. The openness toward new possibilities – or more synthetically, the very development of the possible – defines a field that becomes self-gendered at every moment (Van Geert, 2003). This fundamental unpredictability that characterizes the creation of novelties and freedom has, however, limits. The paradox is that, like the development of any complex system, they cannot be foreseen. Their definition will always be given *après-coup*, once two moments of the process are known and compared. But retrospectively, an area of possible development with strong restrictions could be identified. The limits will always be fuzzy, as in Waddington’s epigenetic valleys. However, they allow us to highlight the involvement of different forces that, like attractors, modulate change (Valsiner, 2018).

The complement to this process of development consists in the creation of necessities (Smith, 2017). Indeed, one might believe that the creation of a necessity, which presents itself to the spirit in the form of a certainty – such as the belief in the persistent existence of objects that are not immediately perceived – is an obstacle to the development of new possibilities. However, necessities must be distinguished from pseudo-

necessities. While the former are the result of a deduction arising from the coordination of preceding possibles, and are the source of new unpredictable possibles prior to the conformation of the necessity in question, pseudo-necessities, on the other hand, are a certain limit to new creations (Piaget, 1983). They do not result from new co-ordinations – and are therefore not a genuine development – and find their strength in affective or ideological complexes. For example, Aristotle attributed a pseudo-necessity to rectilinear movements, which resulted in the bizarre angular representation of the trajectory of projectiles (Piaget, 1981). Pseudo-necessities that do not come from a deductive process based on the coordination of different possibilities are a constraint for the imagination and for development. In biological terms, it is a process comparable to hypertrophy. In this sense, the crucial role of the coordination of possibilities for development, both in the domains of specific scientific disciplines and in models of convergence, is a hypothesis that deserves further research.

Proposition · Inference · Contingent · Necessary · Impossible · True · False · Tautology · Possible world semantics

Introduction

The first aim of logic, since Aristotle, is to establish what are the valid *inferences*, that is to say, in what circumstances a proposition “necessarily” follows from other propositions. To take a very simple example, it can be said that from the two propositions (premises) “if it’s raining, the grass grows” and “it is raining,” the proposition (conclusion) “the grass grows” necessarily follows. But this can also be expressed as: It is “impossible” for the two premises to be true and to the conclusion to be false. Here appears the two notions of *necessity* and *impossibility* which are “alethic” modalities. But it seems that there is still no room for a third notion, that of “possibility.” So the question is: Is possibility a logical notion? It will be shown that the answer is: no.

Standard Propositional Logic

As it is now usual, logic takes the form of a calculus in a formal language. This formal language has a very simple grammar. The simplest part of logic is the “propositional calculus” (PC), and it is sufficient for what will be said in this chapter.

The “vocabulary” of the language for this calculus is composed of the following:

- A (countable infinite) set P of *proposition letters*, $p_1, p_2, \dots, p_n, \dots$, which are supposed to represent “elementary” propositions, that is to say propositions that cannot be analyzed into other propositions, for example, “the cat is on the mat.”
- A set of *propositional connectives*; the most usual ones are the negation, $\sim$, the conjunction, $\wedge$, the disjunction, $\vee$, the implication, $\Rightarrow$, and the bi-implication, $\Leftrightarrow$.
- A set of “improper” symbols: brackets, square brackets, braces, etc.

The *rules of formation*, which define the well-formed formulas (wff) of the language, are as follows:

- A propositional letter alone is a wff.
- If ϕ et ψ are wff, so are $\sim\phi$, $\phi \wedge \psi$, $\phi \vee \psi$, $\phi \Rightarrow \psi$ and $\phi \Leftrightarrow \psi$.

As only the semantics of this language is of interest in this chapter, it is not required to present the “rules of inference” (but the reader will be supposed to be familiar with the notion of an axiomatic system). The semantical properties of the connectives are the following:

- A negation $\sim\phi$ is true if, and only if (iff), ϕ is false.
- A conjunction $\phi \wedge \psi$ is true iff ϕ and ψ are true.
- A disjunction $\phi \vee \psi$ is false, iff ϕ and ψ are false (it is the inclusive “or”: Both propositions can be true).
- An implication $\phi \Rightarrow \psi$ is false iff ϕ is true and ψ is false (ϕ is called the *antecedent* of the implication, ψ its *consequent*).
- A bi-implication $\phi \Leftrightarrow \psi$ is true iff ϕ and ψ are both true or both false.

An important theorem will be admitted in the following: $\phi \Rightarrow \psi$ is a logical truth (a tautology) iff the inference from ϕ to ψ is valid. As all the formulas of the language can be transformed into implications, the aim of the propositional calculus is to show what are the tautologies.

In our example above, there are two elementary propositions only: “it is raining” and “the

grass grows.” The inference corresponds to the implication: $[(\text{it is raining} \Rightarrow \text{the grass grows}) \wedge \text{it is raining}] \Rightarrow \text{the grass grows}$. It can easily be shown that this proposition is logically true (is necessarily true). Suppose first that the two members of the conjunction in the antecedent are true, then the antecedent of the implication “it is raining $\Rightarrow$ the grass grows” is true (it is the second member of the conjunction), and so, by definition of “ $\Rightarrow$ ”, the consequent (“the grass grows”) must be equally true, but this consequent is precisely the consequent of the principal implication. Thus, the two members of the principal implication are true, which means that the whole proposition is true. If, on the other hand, one of the two members of the conjunction in the antecedent were false, the conjunction would be false and so the whole proposition would be true.

Now, can this proposition be false? For it to be false means that the antecedent of the principal implication is true, and the consequent false. But it has just been shown that this cannot be the case, so it is impossible for the whole proposition to be false, and it can only be true: It is necessarily true. All the propositions of logic (tautologies) are necessary truths and their negation necessary falsehoods.

The semantical approach gives a precise meaning to those notions. Two fundamental theses of PC are here presupposed. (1) The elementary propositions are logically independent of each other, i.e., an elementary proposition is true or false independently of the truth or falsity of any other elementary proposition. (2) The truth-value of a “molecular” proposition ϕ is uniquely determined by the truth-values of the elementary propositions occurring in ϕ (the propositional connectives are said to be “truth-functional”).

Returning to the formal language, an “interpretation” of the proposition letters must be given that is to say a function i from the set P to the two-elements set $\{T(\text{true}), F(\text{false})\}$ ($i: P \rightarrow \{V, F\}$). Then, given an interpretation i , it is possible to calculate the truth-value of a molecular formula ϕ for i because: first, a formula is always of finite length; second, only the values given by i to the proposition letters in ϕ are to be taken into account in virtue of the thesis of the logical

independence of the elementary propositions; and third, the result is uniquely determined by *i* in virtue of the truth-functionality of the connectives.

Thus, if *n* different proposition letters occur in a formula ϕ , there is only 2^n different interpretations for the *n* proposition letters, and this makes possible to check whether ϕ is true for all, for none, or for some of those interpretations. There are various methods to do this, the simplest one being that of the “truth-tables.” For example, let ϕ be: $[(p_1 \Rightarrow p_2) \wedge \sim p_1] \Rightarrow \sim p_2$, and ψ (which corresponds to our example above): $[(p_1 \Rightarrow p_2) \wedge p_1] \Rightarrow p_2$. As the same two proposition letters occur in those two formulas, there are only four (2^2) relevant interpretations for the two formulas; the truth-tables for ϕ and ψ take the following form:

		φ										ψ					
		p_1	p_2	$[(p_1 \Rightarrow p_2) \wedge \neg p_1] \Rightarrow \neg p_2$								$[(p_1 \Rightarrow p_2) \wedge p_1] \Rightarrow p_2$					
1	T	T			T	F	F	T	F			T	T	T	T		
2	T	F		F	F	F	T	T				F	F	T	T	F	
3	F	T		T	T	T	F	F				T	F	F	T	T	
4	F	F		T	T	T	T					T	F	F	T	F	

Under p_1 and p_2 , on the left, are the four relevant interpretations for ϕ and ψ . To each of these interpretations corresponds an infinite set of different interpretations $i: P \rightarrow \{T, F\}$, which all coincide on p_1 and p_2 . It is easy to see how the truth-values of ϕ and ψ are calculated given the interpretations of p_1 and p_2 .

ψ is true for all the interpretations, as it was expected from the informal discussion of this formula. As there are no other relevant interpretations for ψ , ψ cannot be false; it is necessarily true and its negation is necessarily false (it is an “impossible truth,” a contradiction).

On the other hand, ϕ is false for the third interpretation, so it is not a tautology (it is not a necessary truth), but it is true for the other three interpretations, so it is not a contradiction. Being neither necessary nor impossible, it is *contingent*.

In the formal language for PC, there are, thus, from a semantical point of view, three kinds of formulas: the *tautologies* (necessary truths), the *contradictions* (impossible truths), and, in the middle, the *contingent* truths (which are also contingent falsehoods):

It is raining or it is not raining	The cat is on the mat or is eating	It is raining and it is not raining
Necessary	Contingent	Contradictory/impossible

It must be noticed that all the proposition letters represent contingent (elementary) propositions, since for each proposition letter p_i there are two interpretations: $i(p_i) = T$ and $i'(p_i) = F$. That is to say: All the elementary propositions are contingent; it is a corollary of the thesis of the logical independence of the elementary propositions.

And now comes the question: What about of the *possible*? One is tempted to think that the true meaning of the possible is *contingency*: When it is said that it is possible for John to come, it is presupposed that it is also possible for him not to come. When the police try to find the murderer of a woman, it suspects, for example, her husband and her lover: It is possible, but not necessary, that the murderer was her husband (for he is known to be a jealous man), but it is as well possible, but not necessary, that the murderer was her lover (for he is known to be a violent man), and so on. . . And when the murderer has been discovered, say the lover, nobody would say that “the lover is the murderer” is a necessary proposition: It is true but not necessary, so it is a contingent proposition. Thus, it is not surprising that this meaning was the first Aristotle considered at the beginning of his investigations about the modalities (cf. *An. Prior*, 8, 29b 30, 13, 32a 32).

Yet, this meaning has not been retained by the logician. Traditionally, the possible has been defined as the noncontradictory (Leibniz: “*Possibilia sunt quae non implicant contradictionem*”). Thus the “possible” covers the contingent *and* the necessary:

It is raining or it is not raining	The cat is on the mat, or it is eating	It is raining and it is not raining
Necessary	Contingent	Contradictory/impossible
Possible		

In an axiomatic system for the calculus of propositions, the only propositions that can be proved and the only that can appear in the system are the necessary ones; admittedly, they can be

said to be “possible,” but it is not their possibility which is of interest. Their possibility is only a useless by-product of their necessity. In the semantical treatment of the calculus of propositions, as above, a distinction can be made between the contingent and the necessary, but to show that a formula is “contingent” is only a way of showing that it is *not* a tautology.

The idiom of the necessity, impossibility, etc. belongs to the commentaries *about* the formulas of the formal language, but instead of speaking of the necessity (impossibility) of a proposition represented by a formula, it would be as well to speak of a proposition represented by a formula proved in the axiomatic system, or true for all interpretations. Thus, the modal idiom may seem useless.

Nevertheless, this idiom is not completely deprived of interest. For it can be said that the negation of a necessary proposition is a contradiction (is impossible), or that the negation of a contradiction is at least possible. Thus, there are some simple “logical” relations between the three notions of necessity, impossibility, and possibility which can be represented by the traditional “square of opposition”:

Not possible that not- φ Impossible that not- φ Necessary that φ	Contrary	Not possible that φ Impossible that φ Necessary that not- φ
↓ Subaltern	↖ contradictory ↗ ↙ ↘	↓ Subaltern
Possible that φ Not impossible that φ Not necessary that not φ	Subcontrary	Possible that not- φ Not impossible that φ Not necessary that φ

From this “square of opposition,” it appears that there is a simple relation between the possible and the necessary that can be expressed using negation alone: “It is necessary that φ ” is equivalent to “it is not possible that not- φ ” and “it is possible that φ ” is equivalent to “it is not necessary that not- φ .” In the sequel, the following symbols will be used for these modalities: $\Box\varphi$

$\rightarrow$ “it is necessary that φ ”; $\Diamond\varphi \rightarrow$ “it is possible that φ ” (φ is called the *dictum*). Thus, each one of these two modalities can be defined with the aid of the other and the negation: $\Box\varphi \stackrel{\text{def}}{=} \sim\Diamond\sim\varphi$ or $\Diamond\varphi \stackrel{\text{def}}{=} \sim\Box\sim\varphi$. It is easy to see that these definitions lead to the bi-implications (on the right column of the square above): $\sim\Box\varphi \Leftrightarrow \Diamond\sim\varphi$ and $\Box\sim\varphi \Leftrightarrow \sim\Diamond\varphi$.

On the other hand – and this explains why the possible has been distinguished from the contingent – there are not so simple relations between the contingent and the other modalities, since “ φ is contingent” is equivalent to $\sim\Box\varphi \wedge \Diamond\varphi$. Thus, “ φ is contingent” implies that “ $\sim\varphi$ is contingent” since $\sim\Box\sim\varphi \wedge \Diamond\sim\varphi$ is equivalent, by definition, to $\Diamond\varphi \wedge \sim\Box\varphi$, and from “ φ is not contingent” nothing determinate follows since this can mean *either* $\Box\varphi$ *or* $\sim\Diamond\varphi$.

On this basis, Aristotle already tried to build a “modal logic”, which was, to be sure, rather confused, but in the last century this logic has been developed more rigorously, even if it has been severely criticized by some logicians.

Modal (Propositional) Logic (MPC)

MPC is an extension of PC. So the formal apparatus of the MPC is simple: It is the formal language of PC to which the two symbols for the modalities, $\Box$ and $\Diamond$, are added (but one of them is sufficient; the other may be introduced by definition). To the rules of formation of the language for PC are added the two rules:

- If φ is a wwf, then $\Box\varphi$ is wwf.
- If φ is a wwf, then $\Diamond\varphi$ is wwf.

Those modal operators do not behave semantically like the propositional connectives since they are not “truth-functional”: If φ is true, the truth-value of $\Box\varphi$ is not determinate: it may be true as well as false, and if φ is false, the truth-value of $\Diamond\varphi$ is no more determinate: it may be false as well as true. Thus, the fundamental principle (2) above of PC is not satisfied; in other words: It does not suffice to give an interpretation of the propositional letters occurring in a modal

formula, to be able to calculate the truth-value of this modal formula.

From this, it follows that neither truth-tables nor any other method, available in propositional logic, can be used to ascertain whether a modal wwf is a modal logical truth or not, that is to say: There is no fixed set of modal logical truths, while there is a fixed set of PC-tautologies.

At the beginning of the revival of the modal logic (in the years 1920–1930), some logicians – the most famous being C. I. Lewis – tried to overcome this difficulty by building various axiomatic systems for MPC, in view of testing the plausibility of a modal proposition by taking into consideration its logical consequences. But which modal propositions may be taken as axioms? There are various candidates. The most obvious is one which had been stated by Diodore (end of the fourth, beginning of the third century BC) in his famous “Master Argument”: $\Box(\varphi \Rightarrow \psi) \Rightarrow (\Box\varphi \Rightarrow \Box\psi)$. All the “normal” systems of modal logic include this axiom, which is called **K**.

The other candidates are more or less evident. One which is quasi, as obvious as **K**, states that a necessary truth is, *a fortiori*, true: $\Box\varphi \Rightarrow \varphi$ (called **T**). If $\sim\varphi$ is substituted for φ , this is equivalent, by contraposition, to: $\varphi \Rightarrow \Diamond\varphi$, which is an old principle already admitted by Aristotle or Leibniz, for example (“Tout ce qui est actuel peut être considéré comme possible” Letter to A. Arnauld, 1686/7/4, p. 120). Another one, more problematic, is: $\Box\varphi \Rightarrow \Box\Box\varphi$ (called **4**), that is to say: What is necessary is necessarily necessary. For example, Descartes thought that the necessary truths (for us), like $7 + 5 = 12$, are free creations of God which means that God would have been susceptible to change his mind and to decide that $7 + 5 = 11$. For Leibniz, on the contrary, the necessary truths are also necessary for God.

Two other principles are also traditionally studied: $\varphi \Rightarrow \Box\Diamond\varphi$ (**B**) and $\Diamond\varphi \Rightarrow \Box\Diamond\varphi$ (**5**).

Different combinations of those principles result in different systems of modal logic; the most current are as follows:

- The system *K*: **K** alone
- The system *T*: **K+T**
- The system *S4*: **K+T+4**

- The system *B*: **K+T+B**
- The system *S5*: **K+T+5**, or **K+T+4+B**

It is said that a system is stronger than another, when all the theorems of the second are also theorem of the first. This relation between the modal systems can be represented like this:

$$K \rightarrow T \begin{matrix} \nearrow^{S4} \\ \searrow^B \end{matrix} S5 \quad (“K \rightarrow T”: T \text{ is stronger than } K, \text{ etc.})$$

As MPC is an extension of PC, all the tautologies of PC are logical truths of MPC and can be taken as axioms. Furthermore, in those axiomatic systems, one the rules of inference is the *rule of necessitation*: If φ is a theorem, then $\Box\varphi$ is a theorem of MPC. Thus, if φ is a tautology, $\Box\varphi$ is a theorem of MPC, as it was expected.

Each one of those systems is consistent, and there is no *logical* reason to adopt one of them rather than any other. But for semantical reasons which will be expounded below, most of the philosophers prefer the system *S5*.

Nevertheless, all those systems share an important feature: *All* the theorems of MPC are transformed into tautologies of PC by deleting all the modal operators in the MPC-theorems (this can be easily proved). This can be illustrated by the case of the axioms above: **K** is transformed into $(\varphi \Rightarrow \varphi) \Rightarrow (\varphi \Rightarrow \varphi)$, and for the other axioms, their propositional transform is always $\varphi \Rightarrow \varphi$. It is clear that these PC-formulas are tautological. From this, it follows that if a PC-formula φ is possible but nonnecessary, i.e., *contingent*, $\Diamond\varphi$ is of course well formed, but cannot be a theorem in MPC since its propositional transform is not a tautology. Thus, if φ is a wwf of PC, the only formulas of the form $\Diamond\varphi$ that can be MPC-theorems are those in which φ is a tautology of PC.

All this can be seen more perspicuously if a semantical point of view is adopted. The semantics for MPC has been elaborated in the years 1950–1960 by logicians such as Kripke or Hintikka. It finds its inspiration in the leibnizian idea of the existence in the mind of God of an infinity of *possible worlds*. But there is a less theological and more logical origin of this idea:

As it has been said, the formal language for PC contains an infinite set of propositional letters; these letters must be interpreted in order to evaluate a given formula for a given interpretation. Each interpretation gives to the propositional letters the value true or the value false; thus, to each interpretation corresponds a “world” in which all the formulas interpreted as true represent existing states of affairs in this “world,” and, conversely, all the formulas interpreted as false represent non-existing states of affairs in the same “world.” Obviously, as a tautology is true for all interpretations, it is true in every “world.”

It is clear that this idea must be more elaborated to fit the diversity of the MPC-systems and the fact that the modal operators are not “truth-functional.” The core of the semantics for MPC is that only some worlds are *accessible* from a given world (or that a world can *see* only some worlds). Consequently, the evaluation of a modal formula is more complicated than that of a PC-formula. It is necessary to fix: first, a set W , finite or infinite, of “worlds” $w_1, w_2, \dots$; second, a relation R between these worlds such that if $w_i R w_j$ then w_j is *accessible* from w_i (or w_i *sees* w_j); and third, the interpretation of the propositional letters in each world belonging to W , that is to say a function i from P to $\wp(W)$ ($\wp(W)$ is the set of the subsets of W); intuitively, $i(p_i)$ is the subset of W such that p_i is true in each world belonging to this subset.

So, a *model* for MPC is a triplet: $M = \langle W, R, i \rangle$. In each world, a PC-formula is evaluated as usual in PC (truth-table). But the evaluation of an MPC-formula in a world requires two new rules for the modalities:

- $\Box\phi$ is true in the world w_i iff, for every world w_j such that $w_i R w_j$, ϕ is true in w_j .
- $\Diamond\phi$ is true in the world w_i iff, for at least one world w_j such that $w_i R w_j$, ϕ is true in w_j .

An MPC-formula ϕ is *valid in a model* M iff it is true in all the worlds belonging to W . In this case, M is said to be a model for ϕ . But this is not sufficient: ϕ may be invalid in a different model $M' = \langle W, R, i' \rangle$, that is to say ϕ may be false in at least one world in W for an interpretation $i' \neq i$.

$\langle W, R \rangle$, where W and R are supposed fixed, is called a *frame*. To get a model, it is necessary to fix an interpretation; if this is done, it is said that the model obtained is *based on* the frame $\langle W, R \rangle$. Thus, there are as many models based on $\langle W, R \rangle$ as there are different interpretations of the propositional letters. An MPC-formula is said to be *valid in a frame* iff it is valid in all models based on the frame.

But this is not the end of the story. In general, a relation R , defined on a domain, may have some *formal* properties; for example, it may be *reflexive*, that is to say each element of the domain has the relation R to itself; it may be *transitive*: if xRy and yRz , then xRz , for all x, y, z belonging to the domain. It may be *symmetric*: if xRy then yRx , for all x, y belonging to the domain. When a relation has these three properties, it is said to be an *equivalence relation*.

Now, the set of worlds in a frame and the interpretations may vary and the relation may have some of the properties above. For example, let the relation R be reflexive. The *class of reflexive frames* is the class of frames in which the relation is reflexive, regardless of the set W and the interpretation i . *Idem* for the class of transitive frames and the class of symmetric frames.

An MPC-formula is *valid in a class of frames* C , if it is valid in all the frames belonging to C . The main result proved by logicians like Kripke is that a determinate class of frames corresponds to each of the systems above, that is to say: A formula is a theorem in one the system, iff it is valid in its corresponding class of frames. This sheds some light on the nature of those systems.

To the system K , corresponds the class of all frames, so the properties of the relation are indifferent.

To the system T , corresponds the class of reflexive frames; to the system $S4$, the class of reflexive and transitive frames; to the system B , the class of reflexive and symmetric frames; and to the system $S5$, the class of reflexive, symmetric, and transitive frames, that is to say the class of frames in which the relation is an equivalence relation.

For sake of simplicity, but without loss of generality, it can be assumed that in the models

for *S5*, each world “sees” every world belonging to the sets *W* of these models (in this case, *R* is said to be *universal* in its domain). This is why the *S5*-models are more akin to the Leibnizian idea than are the models for the other systems and why this system is frequently favored by philosophers. Nevertheless, it must be remembered that there is a plurality of *S5*-models, and this is not leibnizian, since, for Leibniz, God sees every possible world so that there is only one model for him.

It has been said above that in no system, a formula of the form $\Diamond\varphi$, where φ is a PC-contingent, can be a theorem. This can be made more intuitive by considering the *S5*-models (as *S5* is the strongest system, the following holds equally for the other systems). To show that a formula of this form is not valid in the class of the *S5*-models, it is sufficient to show that it is not valid in one *S5*-model. This is possible because, as φ is PC-contingent, it is always possible to define an interpretation *j* such that φ is false in every world in the model $M = \langle W, R, j \rangle$. For example, let φ be $p_i \Rightarrow p_j$ which is false for an interpretation *i* iff $i(p_i) = T$ and $i(p_j) = F$. Then *j* can be so defined that $j(p_i) = W$ and $j(p_j) = \emptyset$. That is to say, p_i is true for *j* in every world, and p_j is true in no world (i.e., false in every world). Thus, for *j*, $p_i \Rightarrow p_j$ is false in every world, and, as each world in *W* can see every world, no world can see a world in which $p_i \Rightarrow p_j$ is true, so $\Diamond\varphi$ is false in every world.

Another example is as follows: Let φ be $p_i \wedge p_j$ which is false for an interpretation *i* iff $i(p_i) = F$ or $i(p_j) = F$. Then *j* can be so defined that $j(p_i) \cap j(-p_j) = \emptyset$. That is to say, p_i is true for *j* in all the worlds in which p_j is false, and conversely. Thus, $p_i \wedge p_j$ is false for *j* in every world in *W*, etc. (see above).

Of course, in other *S5*-models, those same formulas can be valid, but no model can “see” another model. Thus, if φ is not valid in a model *M*, but valid in a model *M'*, the nonvalidity of φ in *M* is not affected by the validity of φ in *M'*. On the other hand, if there were only one model, if all the possible worlds corresponding to the different interpretations of the propositional letters were in the set of worlds of this model, and if the relation *R* of this unique model were universal,

then all the formulas of the form $\Diamond\varphi$, φ representing a possible but non-necessary proposition, would be true in all the worlds. R. Carnap devised such a semantics, but, unfortunately, it appears that it cannot give rise to a satisfactory logic.

Thus, between the necessary and the contingent (possible but non-necessary) there is an asymmetry in MPC: As it has been said, if φ is a tautology (necessary proposition) of PC, $\Box\varphi$ is an MPC-logical truth; on the contrary, if φ is a possible but non-necessary proposition in PC, $\Diamond\varphi$ is *not* an MPC-logical truth.

This asymmetry reveals something important: The fact that a proposition is possible but not necessary is *not* a logical property of the proposition. A proposition is a tautology in virtue of its *form* alone, which means that it is possible, in the formal language for PC, to substitute uniformly for each proposition letter in a tautology any formula, the result remaining always a tautology. On the contrary, in a possible but non-necessary formula, this operation may lead to a contradiction or to a tautology. It is this fact which makes it possible to define a *S5*-model in which a formula representing a contingent proposition is false in every world. Thus, contingency is not a *formal* property of a contingent proposition, so it cannot be logically determined whether a proposition is possible but non-necessary.

In more philosophical terms, this means that what is possible but non-necessary could be either always actual or never actual; this is just a question of fact, not of logic.

Conclusion

It may be objected that in MPC a lot of laws involve the operator of possibility, starting with the axioms **B** and **5**. It is easy to see that this objection is not justified.

In general, MPC may be described as the study of the interactions of the modalities in the tautologies of PC. Nevertheless, this cannot lead to change something to the previous remarks. For example, let φ be $\Diamond(p_1 \wedge \sim\Box p_2) \Rightarrow \Diamond(\Diamond p_1 \wedge \sim p_2)$ which is *S5*-valid. Thus if the antecedent of this

implication is true, necessarily, the consequent is true: The inference from the antecedent to the consequent is valid. But the antecedent could be false: It is sufficient to consider a *S5*-model such that $i(p_1) = \emptyset$. So $p_1 \wedge \sim \Box p_2$ is false in all the worlds of this model, and consequently $\Diamond(p_1 \wedge \sim \Box p_2)$ is also false in all the worlds: $\Diamond(p_1 \wedge \sim \Box p_2)$ is not *S5*-valid. To be sure, the implication is valid in this model, but the consequent $\Diamond(\Diamond p_1 \wedge \sim p_2)$ cannot be valid in *S5*, since the antecedent of the implication is not valid. In other words: Neither the antecedent nor the consequent is valid.

This may be generalized and is just a manner to encounter again what had been established above.

Possible in Management

Joel T. Schmidt and Christian H. Werner
Institute for Creativity and Innovation,
Hochschule für angewandtes Management
GmbH, Ismaning, Germany

Abstract

This entry explores the transformative power of the “possible” in the field of business and management by using digital transformation as an overarching framework. Given the rapid advancement of technology and its impact on

business innovations, including both internal processes at all levels of operation and external processes enabling business transactions with customers and partners, digitalization elements are drivers of change and cannot be left out of any considerations of future potential or possibilities. This entry examines how digitalization is changing organizational structures and how agile management methods are used to manage innovation. It provides an overview of business models which are possible within digital business environments, including digital marketplaces and platforms, as well as models that can be used in open innovation. Finally, the entry identifies contradictory tensions inherent to innovation processes in digital transformation and how the management of paradoxes enables organizations to create their own possible futures.

Keywords

Digital transformation · Innovation management · Digital business models · Agile methods · Open innovation · Paradox mindset

Introduction

It's the end of the world as we know it ... (R.E.M. 1987)

Considering the transformative power of the “possible” within the context of business and management, other words and synonyms spring to mind: potential, achievable, doable. At a closer look, the meaning of possible, the definition includes the aspect of a conditional future, which may (or may not) occur depending on the right conditions (Merriam-Webster [n.d.](#)). Limitations often inhibit the realization of possibilities, changing dreams and aspirations into the disappointing reality of impossibility. Both sides of the coin need to be considered in the context of business and management, for it is this inherent ambivalence that opens the door to explore the arena of business innovation, creativity, and its management. The rise and fall of entrepreneurs, the innumerable iterations of new product design, the windows of opportunity

presenting themselves during times of instability and economic downturn, or the massive impact of changes currently occurring in response to transformation processes in the paradigm shift from mechanical to digital. As the lyrics of the R.E.M (1987) song so aptly put it, the world is indeed ending as we know it, but possibilities abound. Under the backdrop of digital transformation, the possible in business and management is presented in this entry as it is impossible to separate digital from the future.

Although digital transformation provides a future framework for what is possible in business and management, it is at once both complex and unclear. Given the incredibly fast pace of technological change in this context, existing management theories and models are rapidly becoming obsolete, ineffective, or simply inefficient, as the rules of the game are changing (Harwardt and Schmutte 2020). The common practice of companies and managers to evaluate actions in Drucker's (2009, p. 2) terms of what is efficient (doing things right) and effective (doing the right things) is intensified with the speed and disruptive nature of digital change. The need for constant awareness and analysis of the future forces companies to engage in strategic management, which according to Macharzina (1999) means the proactive creation of the future (as cited in Schwarz 2008, p. 239).

Recognizing the need for creativity and innovation as companies create the future, it is important to adopt an integrated approach going beyond the dichotomy of ideation (creativity) and implementation (innovation). Tang (2017) encourages managers to view creativity as a driving force over the entire innovation process, with repeating cycles of creative ideation occurring until implementation is achieved. The key to success in this approach is managing the processes effectively recognizing the distinguishing characteristics of creativity (novelty and originality) and innovation (practicality and effectiveness), and finding a balance using both to overcome the limitations and constraints of creativity (personal and intra-individual) and innovation (social and inter-individual) (Werner and Tang 2017).

Digital = Agile

Understanding what is possible for the future also requires awareness of the present and analysis of the past. The phases of technological change driving digital transformation are presented in Fig. 1, which integrates two common frameworks: the German/European framework from manufacturing termed Industry 4.0, and its American equivalent termed Internet of Things (IoT). Both frameworks illustrate the current phase of digital transformation within an historical context.

Schlöpfer and colleagues from Deloitte (2015) depict Industry 4.0 as part of a series of technological revolutions over time, starting with steam-power. With each revolution, the achievable output of new products surges forward, surpassing the limits of what was possible in the past, leading to new innovations and potential for further development in the future.

The three waves of IT-driven competition described by Porter et al. (2014, 2015) show the development of electronics and computer technology, culminating with IoT. Each wave represents the technological changes in terms of product features, functionality and capability. It is important to consider how the competitive business environment is impacted by technology, as management decisions involve knowledge and understanding of internal potential for innovation (production), and sensitivity for what is achievable in the external marketplace where products and services are sold and distributed in ways which are distinguished from other players in the field (competition).

Agile Organizations

The possibilities resulting from digital transformation demand new structures for management, control and performance, yet businesses are changing more slowly than technology. As the gap between the potential for profit offered by technological advancement and the actual real performance or productivity of businesses exponentially increases (Bersin et al. 2017b), it becomes clear that the real problem is not technical, but rather organizational, in terms of how organizations use human capital, or "how

Possible in Management, Fig. 1 Timeline of industrial revolution and IT-driven competition. (Adapted from Schlöpfer et al. 2015; Porter et al. 2014, 2015)

businesses organize, manage, develop and align people at work” (p. 3). A response to this challenge is the shift to agile processes with a stronger focus on personal commitment, the ability to think creatively and to solve problems independently, rather than remaining entrenched in the routine processes of fixed hierarchical structures (Mohr 2020). Digital technologies are utilized in business processes, such as software-supported project management including task assignment and coordination and real-time communication, as they further reduce the need for hierarchical structures and enable flatter hierarchies and decentralized project teams without losing clarity or control. Organizations with flat hierarchies have the potential to be more effective and faster than traditional organizational systems, but there is no guarantee.

The transition from hierarchical to agile organizational structures is illustrated in Fig. 2 by integrating concepts from two studies by leading consulting companies, Deloitte and McKinsey &

Company. The top part of the figure is based on Bersin et al. (2017a) from Deloitte, illustrating how the linear, rigid structure of hierarchies used by traditional companies in the past are incompatible with the demands of current business contexts, which require dynamic, flat and agile structures to effectively compete in fast and complex environments. Features of organizations as “machines”, with traditional hierarchies include top-down processes and high levels of bureaucracy result in departmental structures referred to as “silos”. In contrary, agile organizations as “organisms” operate in heterogeneous teams stimulating interaction that is fluid and non-linear, with leadership that facilitates rather than controls, enabling action and providing feedback and direction.

Agile Methods

Agile methods are also important for individuals and teams in terms of the changing demands of collaboration and optimal functionality regarding

Possible in Management, Fig. 2 Transformation of organizations. (Based on Bersin et al. 2017a; Aghina et al. 2018)

preconditions and requisite skillsets relating to the demands of digitalization for rapid and complex responses (Lipowsky and Schmidt 2016) (see also ► “Collaborative Creativity”). Two well-established agile methods invented by Schwaber and Sutherland (2012, as cited in Lipowsky and Schmidt 2016) are *Scrum* and *sprints*. *Scrum* increases the effectiveness and performance of teams dividing critical roles and responsibilities among team members. Using Scrum gives autonomy and freedom to the team as the tasks describe “only the desired outcome (what), not the way it is to be carried out (how)” (p. 267). *Sprints* represent a series of short iterations for software development where each sprint culminates a presentation of current results, followed by immediate planning for the next sprint. These short phases of development, outcomes and reflection provide flexibility to make ongoing changes and improvements. In this way the innovation process of software development is enabled as a creative process where “experiments and failure are necessary parts of the process” (Lipowsky and Schmidt 2016, p. 268). These examples of agile methods (see also ► “Design Thinking”) help to illustrate how organizations can function as an organism, a

living entity, where its members are essential to the system, requiring self-organization, responsibility and continuous improvement.

Digital Business Models

Recognizing the potential for profit offered by digital transformation means understanding what is possible, in terms of new digital business models. “The essence of a business model is that it crystallizes customer needs and ability to pay, defines the manner by which the business enterprise responds to and delivers value to customers, entices customers to pay for value, and converts those payments to profit through the proper design and operation of the various elements of the value chain” (Teece 2010, p. 191).

Three possible areas of activity helping companies to benefit and profit from digital technology (Deiser 2018, p. 12) are presented in Fig. 3, including saving (by optimizing efficiency and effectiveness; making more money (by improvement of existing products); and making new money (by creation of new revenue opportunities). The third area is where digital transformation can have the

AREAS OF DIGITAL TRANSFORMATION	FEATURES AND DESCRIPTION			
	Role of Digital Technology	Business Impact	Type of Change	Impact on Operating Model
Save Money	Improve processes	Cost convenience	Incremental (mainly organization related)	Low
Make MORE Money	Enhance products and services	Growth within current paradigm	Incremental (mainly market related)	Medium
Make NEW Money	Create new markets	Disruptive business models	Radical (market and organization related)	High

Possible in Management, Fig. 3 Areas of digital transformation. (Adapted from Deiser 2018, p. 12)

most impact and where companies can generate the most possible profit. However, there is no guarantee of competitive advantage (Teece 2010), given the transparency of business models, which make them vulnerable to imitation.

The dynamic capabilities for business model innovation in a digital context are presented in Fig. 4. According to Rachinger et al. (2019), at the architectural level, business model innovation occurs in cycles of interaction moving through strategy (planning level) and process (implementation level), with the dynamic capabilities of value creation, value proposition, and value capture driving new developments for customers, in both immediate and possible futures. The value chain, as described here, are key elements for business model success (Teece and Linden 2017; Teece 2018), as proposition of value integrates products and services, customer needs, and geography, while value capture incorporates the revenue model (pricing logic, channels, customer interaction) and cost model (core assets and capabilities, core activities, partner network).

The interplay between strategy and business model innovation can be further understood by activities within the dynamic capabilities of an organization. According to Teece (2018), an organization's ability to engage in sensing (identifying opportunities), seizing (designing and refining business models, as well as resource commitment), and transforming (realigning organizational structure and culture) activities support

sustainable transformation, combining with strategic efforts to anticipate competitor reactions and defense of intellectual property (p. 44). Ongoing innovation of business models is a necessary part of organizational growth, as having the right business model shapes strategy and impacts its feasibility and possible realization in the future.

Digital Platforms and Shared Economy

Digital platforms are a good example of the digital transformation of business and business models and the shift toward future forms of sharing economy. Teece and Linden (2017) define platforms as “a combination of hardware and software that provides standards, interfaces, and rules that allow providers of complements to add value and interact with each other and/or users. Collectively, the platform innovator(s) and the complementors constitute an ecosystem that depends on continued innovation and maintenance of the platform by its owner(s) for success” (p. 10).

Inside this shared ecosystem, the technology of a digital platform enables shared economy or forms of sharing commerce. According to Kong et al. (2020) sharing commerce is “a Web-mediated consumer-to-consumer e-commerce business model where service providers transfer temporary possession of goods to customers for a fee or barter. Buyers and sellers are connected through a technology platform that has been tailored to feature social networking capabilities, handle

Possible in Management, Fig. 4 Dynamic capabilities for business model innovation. (Adapted from Rachinger et al. 2019)

transaction settlement and provide recourse” (Kong et al. 2020). In this way the digital platform provides the framework for the business model. Kong and co-authors describe as interactions between the *service enablers* (who provide the platform marketplace), *service providers* (who own and provide the rented asset), and *customers* (who need the service and are willing to pay for it).

In their description of digital platforms, Teece and Linden (2017) identify two basic types:

- Transaction platforms: facilitate exchanges between buyers and sellers who are not normally connected with each other (a classic example is eBay with its global platform that is easy to use)
- Innovation platforms: provide a base technology and distribution system to which other companies can add their own innovations, increasing the value for the system as a whole (p. 11). A few examples of this type of platform are the Apple “app” ecosystem, or also the computer ecosystem created by Microsoft.

Inherent to the success of both types of platforms is the inclusion of complementors or partners who must first accept the value proposition offered by the platform before it can succeed (Teece and Linden 2017). Exclusive distribution agreements with selected partners may help to

increase the added value, but often complementors participate actively in multiple platforms (p. 11). The risk of imitation exists, but with digital platforms, establishing a partner-base is central to success – simply creating or imitating platform technology is no guarantee.

Insights into the advantages of platform and sharing economy business models can be gained by examining the urban transportation provider Uber. In a comparison of Uber with traditional taxi business model, Teece (2018) identifies a few key features of Uber’s success (p. 43):

- GPS-navigation for drivers: provides predictable response time, enabling identification of the correct location (for both pickup and drop-off)
- Pre-approved credit: shortens the exit time from the vehicle and improves the experience for both customer and driver (and other motorists who may be impacted by the location of the parked vehicle)
- The Uber App: the software platform provides automated logistics integrating the activities and requests of drivers and customers – it is the central element of the Uber business model, since Uber retains control of pricing, not the drivers.

Uber is an excellent example of how successful platform business models are sustainable in terms

of the self-reinforcement that occurs as the user-base increases: “Uber brings the car services to the customer in such an improved manner that some customers see no need to own a car” (Teece 2018, p. 43). According to Teece and Linden (2017), selecting and refining a platform business model is a viable option for leveraging possible future profit and gain in the digital economy, since “companies do not go to market in isolation; in most cases, their products and services become more valuable to customers when combined with the products and services of other firms” (p. 13). Success of such combined and shared platforms of products and services is influenced by the management of trust, which is influenced in turn by social referrals, information quality and the safety of transactions (Kong et al. 2020).

Possible Business Models Using Open Innovation

The concept of open innovation is defined as “a distributed innovation process based on purposively managed knowledge flows across organizational boundaries” (Chesbrough and Bogers 2014, p. 17). These knowledge flows drive innovation as they are acted upon within the framework of an organization’s business model.

Different types of open innovation can be used based on the sources and directional flow of knowledge, including directional flows that are *outside-in* (flowing into the organization from an external knowledge base creating added value for internal processes), or directional flows that are *inside-out* (originating inside the organization flowing out creating added value through external commercialization processes), plus a third type representing *coupled* or bidirectional flows of external knowledge sources and internal commercialization activities. In this model, open innovation creates potential for added value by combining innovation and openness, where “innovation refers to the development and commercialization of new or improved products, processes, or services, while the openness aspect is represented by the knowledge flows across the permeable organizational boundary” (p. 17).

The model of open innovation presented in Fig. 5 offers a comprehensive overview of essential components and how they function in an organization. According to Chesbrough and Bogers (2014, p. 18), open innovation is not limited solely to one functional area of business activity, but can occur in all areas, from upstream research and development (R&D) toward downstream

Possible in Management, Fig. 5 The open innovation model. (Adapted from Chesbrough and Bogers 2014)

activities including manufacturing and marketing. It is important to consider “all activities from invention to commercialization in order to create and capture value from ideas and technologies” supporting business strategy and the effective use of business models to sustain competitive advantage in the current market, to recognize potential for entering and collaborating in other markets, and to create possibilities in new markets (see also ► “Possible in Economics”).

Open innovation provides many ways to support and influence business model development within digital transformation. Saebi and Foss (2015) provide examples of four different types of open business models (see Fig. 6), which can be distinguished from each other based on the dimensions of content (how organizational variables are configured), structure (how the company structures transactions with external stakeholders) and governance (the consequences of those configurations on company performance), as well as the depth and breadth of knowledge search within four distinct open innovation strategies (p. 207).

Business success and the future potential and possibilities of an organization are not solely achieved by innovation strategies, but by their combination with appropriate business models. According to Saebi and Foss (2015), not all open innovation strategies are alike, in terms of how much restructuring of business models is necessary, and finding a match is important, since

different degrees of openness are possible which impact the amount of “permeability to facilitate the in- and outflow of knowledge across organizational boundaries” (p. 210). Recognizing the wide range of possible business model options, empowers organizations to manage the future by actively influencing the outcomes of their innovation initiatives.

Dealing with (Im)possibility by Managing Paradoxes

Within the management of innovation, ambivalent or conflicting perspectives are common and even unavoidable, making balance hard to achieve. Recognizing these tensions as paradoxes helps leaders to manage realizations of the possible more effectively, minimizing the risk of failure or impossibility (see also ► “Risk”). Lewis (2000) developed a paradox framework for management that provides insight into paradoxical tensions which are cognitive or social constructs, reinforced in cycles of defensive reactions to the tensions, and which may be managed by conscious selection of either “acceptance, confrontation or transcendence” (p. 762). The goal is for managers to adopt a paradox mindset, which helps to recognize dichotomies and avoid the trap of unconsciously remaining in either/or contradictions. Management of innovation processes is

Possible in Management, Fig. 6 Four types of open business models. (Adapted from Saebi and Foss 2015)

paradoxical, as innovation demands ambidexterity in order to benefit from both sides of the paradox (Andriopoulos and Lewis 2010). The inherent tensions, conflict, and ambivalence experienced during innovation can lead to frustration and negative emotions inhibiting optimal performance, but by viewing tensions as paradox, managers are able to reduce anxiety, stress, and frustrations intensified by conflicting innovation demands, thereby fueling innovation and increasing the potential of better performance (see also ► “Design Thinking”).

Within the context of digital transformation, the paradoxical nature of innovation is intensified due to the rapid advancement of technology and change, increasing complexity of knowledge (difficulties in processing large amounts of incoming information and data in order to achieve understanding, integration and synthesis for business gain) and the distribution of business and management activities across the dimensions of time and space (engagement of employees and team members outside of local timeframes and geographies). Some example paradoxes include:

Exploitation Versus Exploration

- Exploration requires risk-taking and creation of cutting-edge innovation
- Exploitation requires specialization and efficient allocation of resources

Integration Versus Differentiation

- Integration refers to efforts to align processes and structures in linear formats, often hierarchical and vertical in nature (ease of organization)
- Differentiation refers to operation of self-governed peripheral units connected via horizontal collaboration and exchange (e.g., agile teams)

Freedom Versus Control

- Freedom refers to allowances given to identify emerging market and technological possibilities (no holds barred)

- Control refers to limitations imposed based on existing capabilities, capacities (e.g., manufacturing or distribution) or boundaries (e.g., budget).

Lewis (2000) suggests that the tensions experienced in paradoxical contradictions elicit reactions that accept, confront or transcend the paradox. Ongoing research in managing paradoxes conducted by Andriopoulos and Lewis (2010) encourage managers not to be inhibited or constrained by the tensions falling into the trap of either/or dilemmas in decision on which side to follow, but rather to use the paradox as a source of energy. According to the authors, it is not about “avoiding, fighting or even resolving tensions [...] as pulling too far to one side can prove counterproductive” (p. 106). It is about adopting a paradox mindset that supports finding a balance and developing a fluency with both alternatives, given the unique conditions and necessities of a situation (see ► “Creative Problem-Solving”; ► “Decision-Making”).

Conclusion

It's the end of the world as we know it . . . and I feel fine. (R.E.M. 1987)

Digital transformation represents massive potential for business to make possible futures a reality in terms of growth, performance and gain, but also the flipside of challenge, change, and transformation that can neither be fathomed, nor guaranteed, as digital transformation means changing mindsets resulting in a paradigm shift. Deiser (2018) describes the unavoidable shift “from a 20th century organizational paradigm (command, control, linear processes, silo mentality, stable business models, product orientation, clear industry boundaries, zero-sum game competition) to a new paradigm with participative self-organization, non-linear processes, cross-boundary collaboration, ongoing business model innovation, customer centricity, fuzzy industry boundaries, coopetition, and more” (p. 25). Achieving the possible through digital

transformation means engaging with and implementing new concepts and methods, such as flat hierarchies and alternative organizational structures, agile methods, innovative business models including digital platforms and other networked, collaborative models, as well as the integration of open and shared innovation processes. The possibilities identified in this entry begin with an assessment of what is possible now, but full realization of future potential means committing to an ongoing search for new ways to broaden the scope of the possible in management.

Returning to the initial quotation from R.E. M, which is in itself a paradox, although one that is filled with optimism, efficacy, and empowerment – the world may be ending (as we know it), but who can say what the future has in store, what tomorrow will bring, what is possible? Take a look around, analyze your strengths, weaknesses, and be open for collaboration, and for using the innovation from others to stimulate your own innovation. If there is a gap or problem, fix it, borrow it, make it, create it . . . it is possible.

Possible in Neuroscience

Oshin Vartanian
University of Toronto, Toronto, ON, Canada

Abstract

Historically, human creativity has been associated with flexibility in thinking. Inherent in this view is the importance of the *dynamics* of

thought processes, rather than the stable dominance of any given thought process. In support of this view, there is growing evidence from neuroimaging to suggest that creativity emerges from the dynamic interaction of large-scale networks in the brain – each of which supports a different mode of thinking. Specifically, it appears that the default network (DN) supports spontaneous thought processes that underlie the generation of novel ideas in the mind, whereas the executive control network (ECN) regulates the activity of the DN and other networks to produce output that meets task demands. Indeed, not only is the DN–ECN functional connectivity during divergent thinking correlated with individual differences in creative performance, but it can also be used to distinguish more from less creative individuals based on brain activity at rest. Overall, the interplay between these two brain systems in conjunction with our developing understanding of the neural systems that support imagination is beginning to explain the emergence of useful novelty in the mind.

Introduction

Historically, creativity has been associated with flexibility in thinking (Martindale 1995). Indeed, there is substantial empirical evidence in support of this idea. For example, it has been shown that in creative people the orientation of attention is neither focused nor defocused, but varies flexibly between those states in accordance with task demands (Dorfman et al. 2008; Kwiatkowski et al. 1999; Vartanian et al. 2007; Zabelina and Robinson 2010). Early in the phase of problem solving when the problem space is ambiguous and interference is high, attention is defocused, allowing the entry of a large number of potential ideas into consciousness for consideration. In turn, later in the phase of problem solving when the problem

space is relatively less ambiguous and interference is reduced, attention becomes focused to enable further processing of a few promising kernel ideas towards final solution (Vartanian 2009). Inherent in this view is the importance of the *dynamics* of thought processes, rather than the stable dominance of any given thought process.

Interestingly, there is growing evidence from neuroimaging studies to suggest that creativity emerges from the dynamic interaction of large-scale networks in the brain – each of which supports a different mode of thinking (see entry “► [Creativity](#)”). The basic question involves whether particular patterns of brain activation can explain the emergence of thought that is characterized as creative. Before proceeding further, it is helpful to describe what is meant by the term “brain activation.” Most of this research has been conducted using modern neuroimaging technologies, in particular functional magnetic resonance imaging (fMRI). fMRI is a method that enables one to measure brain activation *indirectly*. Specifically, when neurons in a particular region of the brain need to work harder to satisfy task demands, their metabolic demands become greater. In order to satisfy those increased metabolic demands, more blood is supplied to those brain regions to deliver the necessary oxygen for cellular function. In turn, the uptake of oxygen from the blood by the cells causes a change in the proportion of oxygenated versus deoxygenated hemoglobin levels in the blood, and the magnetic signature of that change is detected by the fMRI scanner. In other words, with fMRI we infer brain activation rather than measure it directly. The advantage of this method is that it is noninvasive and offers very high spatial resolution (i.e., information about *where* the activation is occurring).

Early brain-mapping work in this domain demonstrated two overall findings (for meta-analytic reviews see Boccia et al. 2015; Gonen-Yaacovi et al. 2013; Vartanian 2012; Wu et al. 2015): First, there is no single brain region that drives creativity. Rather, the entire brain contributes to creative cognition. Second, the neural correlates of creativity are process- and domain-specific. For example, there are dissociable neural regions that contribute to creativity in the verbal versus

nonverbal (spatial) versus musical domains. Similarly, there are dissociable neural regions that contribute to processes related to creativity such as analogy versus metaphor, as well as creativity tasks that involve generation versus combination of ideas. As is the case with other higher-order constructs such as reasoning (Goel 2007), this early body of work demonstrated that creativity is hierarchical and componential, and that it emerges from the flexible and dynamic reconfiguration of brain regions that contribute to its various types.

From Brain Mapping to Network Dynamics

More recent work has advanced beyond the search for isolated brain regions to focus on the interaction of large-scale brain networks. These networks were initially discovered using the technique of resting-state connectivity based on which one can identify brain regions that exhibit similar patterns of fMRI activity fluctuations, and can therefore be grouped into large-scale brain systems called “networks” (Zabelina and Andrews-Hanna 2016). Two networks in particular have proven to be central to the emergence of creative thoughts (reviewed in Beaty et al. 2016), although as we shall see later these two networks interact closely with other large-scale networks in accordance with task demands. The first is the default-mode network (DN). Activity in the DN is associated with spontaneous and self-generated thought. Specifically, DN becomes engaged when the individual is not primarily involved in responding to external stimuli, and can engage in activities such as mind wandering (see entry “► [Mind wandering](#)”) and daydreaming (Zabelina and Andrews-Hanna 2016). The second is the executive control network (ECN), which is associated with tasks that necessitate cognitive control. Unlike many other types of cognition in the course of which activations within the DN and ECN are anticorrelated, creativity represents a rare instance in which there is a close coupling (i.e., functional connectivity) between these two systems in the course of cognition (Beaty et al. 2016).

Here the framework by Christoff et al. (2016) regarding the dynamics of thought for

understanding creativity is germane. Within that model spontaneous thought is defined as “a mental state, or a sequence of mental states, that arises relatively freely due to an absence of strong constraints on the contents of each state and on the transitions from one mental state to another” (p. 719). Christoff and colleagues have argued that creativity can be seen as a form of spontaneous thought. However, spontaneous thoughts can nevertheless be constrained by two different types of processes. One type of constraint is deliberate and is implemented through cognitive control. An example of this type of constraint would be when we consciously force ourselves to pay attention to material that we find boring. In contrast, automatic constraints involve mechanisms that operate outside of cognitive control to hold attention on a restricted set of information. An example of automatic constraint would be our inability to shift attention away from a haunting dream. Reinforcing the uniqueness of creativity as a thought process, Christoff and colleagues have argued that creative thinking may be unique among spontaneous thought processes because it likely involves dynamic shifts between deliberate and automatic constraints. Specifically, creativity tends to involve alternation between the generation of new ideas, which is a highly spontaneous activity, and the critical evaluation of these ideas, which is highly deliberate activity (Campbell 1960). From a neuroscientific perspective, the deliberate constraints would be imposed by the ECN, whereas the automatic constraints would arise within the DN as a function of associative processes.

Consistent with this framework, Beaty et al. (2015) used whole-brain functional connectivity analysis to highlight a network of brain regions associated with divergent thinking, which included several regions within DN and ECN (Fig. 1). In addition, their work highlighted the contribution of another large-scale network to the process, namely structures within the *salience network* such as the insula. The salience network has an important role to play in high-level cognitive control and attentional processes because it is involved in the detection and allocation of neural resources to behaviorally relevant stimuli

Possible in Neuroscience, Fig. 1 Cognitive mechanisms of brain network interactions during creative cognition. Notes: *DN* default-mode network, *ECN* executive control network, *VN* visual network. (Adapted with permission from Beaty et al. 2019)

(Bressler and Menon 2010; Menon and Uddin 2010; Uddin 2015). As such, it can trigger the engagement of other networks based on the relevance (i.e., salience) of the task at hand.

Beaty et al.’s (2015) analyses revealed direct functional connections between these three networks in the service of divergent thinking. Specifically, the posterior cingulate cortex (PCC) – a region that lies within the DN – exhibited increased functional coupling with regions of ECN including the dorsolateral prefrontal cortex, as well as regions within the salience network such as the bilateral insula. Using dynamic functional connectivity analysis conducted in the course of engagement in a divergent thinking task (i.e., Alternate Uses Task), Beaty et al. were able to show that the time course of the coupling between PCC and regions within the salience network and ECN varied as a function of the phase of the task. Specifically, PCC showed early coupling with the insula and later coupling with the right dorsolateral prefrontal cortex among other regions. There is evidence to show that one of the roles of the salience network is to facilitate switches between DN and ECN (Cocchi

et al. 2013). As such, its early involvement in the Alternate Uses Task (AUT; Guilford, 1967) could be to facilitate later coupling between DN and ECN. These results highlight the key role that the *dynamics* of network interactions (i.e., transitions) play in the course of creative idea generation.

Data from several fMRI studies including musical improvisation (Pinho et al. 2016) and poetry composition (Liu et al. 2015) have shown that engagement across numerous creativity tasks is associated with dynamic coupling between DN and ECN (see also Ellamil et al. 2012). In this context, DN activity is perceived to reflect the spontaneous generation of ideas or information derived from long-term memory, whereas activity in ECN is understood to reflect evaluative processes that constrain thinking to meet specific task goals. Not only does this dynamic interplay between generative and evaluative processes have a long history in creativity research (Campbell 1960; Martindale 2007; Simonton 2010), but numerous classical models of cognition emphasized the ability of creative people to navigate back and forth between modes of thinking in the service of novel idea generation (Kris 1952). In this sense, the interplay between DN and ECN can be perceived as supporting the interplay between controlled and spontaneous thought processes in the service of novel and useful idea generation.

The case for the importance of DN–ECN functional connectivity in support of creativity is bolstered by two additional bodies of data. First, based on resting-state fMRI data, Beaty et al. (2014) have reported that compared to less creative people, more creative people exhibit greater functional connectivity between DN and regions in the prefrontal cortex that reside within the ECN. This suggests that even when they are not engaged in creative thinking, more and less creative people are nevertheless characterized by different intrinsic patterns of brain function. Second, in a series of studies based on a recently developed method in functional brain imaging analysis – connectome-based predictive modeling – Beaty et al. (2018) were able to identify a pattern of

functional brain connectivity related to high-creative thinking ability consisting of regions within DN, salience network, and ECN. Furthermore, they were able to predict individual creative thinking ability from the same pattern of brain connectivity. These findings suggest that highly creative people are characterized by the ability to simultaneously engage these large-scale brain networks.

Given that DN and ECN are involved in creative cognition, an important question to ask is the specific manner of their interaction. Using dynamic causal modeling (DCM) – an analytic method that makes it possible to test causal hypotheses with fMRI data – Vartanian et al. (2018) probed the specific manner in which ECN controls activation within the DN. They tested two competing hypotheses. According to one hypothesis, ECN might exert unidirectional control over the DN (hypothesis 1). According to that model, DN would generate candidate ideas either through retrieval from episodic and/or semantic memory (or recombination of ideas from memory), which would in turn undergo selection by ECN before a response is outputted. Another possibility might be that ECN and DN might exert bidirectional control over each other as cycles of generation–evaluation are performed before an eventual response is produced (hypothesis 2). This latter possibility is more iterative in nature and acts in the form of successive loops. The analysis of the data, collected using the AUT, strongly supported hypothesis 1. This suggests that ECN exerts unidirectional control over DN in the course of divergent thinking (i.e., ideas are generated by DN and then selected by ECN). It is important to bear in mind that this pattern likely emerged because of the nature of the task used in the study. Specifically, performance on the AUT likely relies on a generation-and-selection sequence that is not iterative, especially given the short time period available for producing responses in the fMRI scanner. Had the task been more elaborate (e.g., story generation), then it is possible that a more iterative and bidirectional effect might have emerged. That possibility needs further examination.

Current Directions: Creativity, Imagination, and the Sensory Cortices

There are a number of contemporary lines of research that are likely to advance our understanding of how the brain generates creative ideas. One line of research involves focus on the psychological and neural bases of *imagination* (see entry “► [Imagination](#)”) – defined as “The power or capacity to form internal images or ideas of objects and situations not actually present to the senses” (Oxford English Dictionary) (see Abraham 2020). It turns out that engagement in imaginative thought might be more prevalent than meets the eye. For example, lab studies have shown that 22% of our thoughts are predominantly task-unrelated and imaginative, meaning that they are not triggered by external sensory events (Stawarczyk et al. 2011). This propensity suggests that imagination – as a potential engine for the generation of novelty – must be taken into account in our efforts to understand the contribution of cognitive processes to creativity (Abraham 2018).

Raffaelli et al. (2020) have recently proposed an integrative framework for the neuroscience of imaginative thought. Within their model, imaginative thoughts can be divided into two broad classes that often interact in everyday experience and in the brain. One class of imaginative thought is rooted in contextually specific and perceptually detailed mental imagery. This class of imaginative content is based on vivid and perceptual mental simulations. Furthermore, the medial temporal lobe (MTL) subsystem within DN is hypothesized to support this specific class of imaginative thought. MTL consists of the hippocampus and parahippocampal cortex and is known to play a critical role not only in episodic and autobiographical episodic memory but also in prospective thinking (e.g., imagining future hypothetical events, formulating autobiographical plans, etc.). According to the *constructive episodic simulation hypothesis*, MTL underlies both past and prospective thinking by retrieving and binding different elements from memory to construct mental scenes (Schacter and Addis 2007). As such, it can be seen why it would play a key role in the construction of

imaginative thought driven by contextually specific and perceptually detailed mental imagery.

The second class of imaginative thought encompasses conceptually-abstract, verbal modes of imagination. Such imaginative thoughts encapsulate internal mental processes construed at a much higher level of abstraction, in verbal or symbolic representational format (e.g., internal monologue). Raffaelli et al. (2020) have argued that this class of imaginative thought is supported by the dorsomedial prefrontal cortex (dMPFC) subsystem of DN – a cluster of neurons that exhibits sensitivity to social processes requiring participants to mentally shift away from the *perceptual* features of the environment to imagine a different cognitive perspective (Lieberman 2007). This framework can explain how one can have both contextually rich as well as conceptually abstract classes of imaginative thought that are supported by the visual and verbal modalities and offers fertile ground for testing hypotheses about the involvement of specific subsystems within DN in support of each class of imaginative thought.

Finally, there is growing appreciation that the networks primarily involved in creative cognition also interact with other large-scale networks in support of this psychological capacity. For example, Beaty et al. (2019) have recently offered an up-to-date account of the network dynamics account of creative cognition in the brain, identifying three classes of cognitive processes that contribute to network interactions during creative performance: (1) goal-directed memory retrieval, (2) prepotent-response inhibition, and (3) internally focused attention, linking each process to the interaction of dissociable networks (Fig. 1). Of particular interest here is a structure within ECN referred to as the anterior inferior parietal lobule (IPL). Not only does IPL support internal attention, but there is also stronger functional coupling between IPL and the visual cortex when attention is internally oriented (Benedek et al. 2016). This suggests that ECN may play a role in the regulation of the focus of attention during divergent thinking by attenuating sensory input (from the visual cortex) and directing

attention to internally generated thought processes. This finding demonstrates that in the context of creative cognition, aside from the DN–ECN coupling, ECN is also interacting with the sensory cortices (e.g., visual cortex) to reduce the impact of external input on internally-generated thought processes.

Summary

Creative cognition is supported by the interaction between large-scale brain networks, in particular DN and ECN. A central idea in this model is the dynamic nature of this interaction in the course of idea generation. The evidence to date suggests that the DN–ECN functional connectivity is related to both variations in performance as well as individual differences in creative ability. Ongoing work on imagination as well as research involving the interactions of these networks with sensory cortices will further our understanding of how the brain supports the emergence of creative thought.

Possible in Performance and Performing Arts

Tatiana Chemi

Aalborg University, Aalborg, Denmark

Abstract

What is possible in performance and performing arts emerges exclusively through relational, bodily, and performative exchanges. Performative experiences occur in the work of ensembles, be it the preparation and experimentation within the group or the *outer* performance for audiences.

Keywords

Ensemble · Performance · Creativity · Activism · Performativity · Theatre

Definition and History

Ensembles can be defined as “a group of supporting [performers]” “producing a single effect” together (from French *ensemble* = together) (Merriam-Webster, Ensemble. Retrieved 20 Aug 2019. www.merriam-webster.com/dictionary/ensemble#h1, 2019). In this entry, *ensemble* is intended as a group whose participants share interest in and commitment to collaborative art-experiences that are performed, embodied, and transformative (Conquergood, TDR 39(4):137–142, 1995).

Performance is here broadly defined as the act of shaping action by means of repetition and/or negation. Etymologically, performance is the co-presence of repetition and/or destruction (*per*), creation or shaping (*form*), and action or movement (*-ance*, suffix shared in words like *dance*) (Fels, A dead Man’s sweater: performative inquiry embodied and recognized. In Schonmann

S (ed) Key concepts in theatre/drama education. Sense Publishers, Rotterdam, pp 339–343, 2011). Performativity theories (Barad, Meeting the universe halfway: quantum physics and the entanglement of matter and meaning. Duke University Press, Durham/London, 2007; Butler, Bodies that matter: On the discursive limits of sex. Routledge, New York/London, 1993; Haraway, Staying with the trouble: making kin in the Chthulucene. Duke University Press, Durham/London, 2016) draw from performance and performing arts the understanding of reality as per-form-ed. However, too often the practical, embodied, en-fleshed origin of these reflections is forgotten or ignored. Looking at ensembles as working group and as metaphor can contribute to hold on to the tangibility of social performativity (Goffman, The presentation of self in everyday life. Harmondsworth, London, 1978) and of participatory creativity (Clapp, Participatory creativity: introducing access and equity to the creative classroom. Routledge, London/New York, 2016). This perspective can contribute to extend the understanding on what performance and performing arts can make possible in society.

Performance as Activism

Several developments in creativity studies (Adams and Owens 2015; Harris 2014, 2016; jagodzinski 2015) sustain the intersection between creativity and the political: in order to imagine and establish new, appropriate models of democratic responsibility, it is necessary to think critically and act creatively. Creativity becomes a fundamental competence, core to democratic participation that can empower individuals and communities in reclaiming their own agency through collective action, a form of creative ensemble performance. Critiquing discourses of talent, genius and high-achieving individuals is necessary to address ensembles' creativity and its potential for critical pedagogy and democratic change in the world. Here, the body that presents itself as other (Allern 2002) participates in other bodies' presentations of "what is" here and now

(Geertz's "thick descriptions," 1973) or "what might be" in the future (for instance, Dolan's "utopian performative," 2001 or Spry 2016). The performer's creativity is an act of agency and activism, not per definition but per practice. Acting is about making visible actions and reactions in a dramaturgically coherent structure and in entangled relationships with others. Acting is a creative act that can only be performed *together* with others: with, around, against colleagues in the ensemble but also for, with, to, in spite of spectators. According Barad (2007), "knowing is a material practice of engagement" (p. 89) and knowing in ensembles cannot but be collaborative and participatory. This is not to say that performative interventions do necessarily achieve positive aims (Barnes and Coetzee 2014), especially when explicitly framed as activist societal change.

With its origin from the ancient Greek verb *theaomai*, to look (Etymonline 2019), theatre indicates the act of looking at repeatedly or of pondering. This action is a multiple negotiation of visible and invisible practices that occur in tangible and culturally codified spaces (Barba and Savarese 2019): onstage activities reified in frontal or closeup expression (visibility, stage) and offstage hidden actions (back, scene). When Goffman (1978) explained the dynamics of social roles, he turned to these performance-proper shifts between front and backstage and also to the audience's ability of shaping actions that are intelligent, sustainable and appropriate, and *ergo* creative and potentially educative. Theatre and performance give access to living third spaces (Bhabha 1994) for its participants (the makers and the spectators). According to Bhabha (1994), third spaces are "hybrid sites of cultural negotiation" (p. 178), and performance is nothing but a third dimension for encounters (Barba 1995). The performing space is potentially activist and empowering, because it enables opposites to coexist (destruction/making, construction/deconstruction, repetition/originality), just like theatre performs in spite of and against the background of oppositions (front/back, visible/invisible, expressed/hidden).

Creativity in Groups and Teams

Obstacles to the understanding of performance as the *locus* of creative possibilities can be the residual tendencies toward individual discourses that feed into instrumental uses of creativity, expected to boost economic growth, techno-industrial development, and critical thinking (World Economic Forum 2018). With origins in romantic and industrialist mind-sets, the idea that creativity is the achievement of individual talent and genius has been influencing centuries of studies (Kaufman and Sternberg 2010). In several reviews (Shaheen 2010; Stein 1974, 1975; Ryhammar and Brolin 1999) that include group level, pressure, and role play, group creativity still relies strongly on the individual as emanating center of creativity. Csikszentmihalyi (1996), Gardner (1993), and Amabile (1983, 1998) investigate environments in organizations and systems but focus on the individual, whose actions are seen as core to any creative initiative.

Alternative perspectives are offered in Harris' creative ecologies (de Bruin and Harris 2017; Harris 2016), where educational environments are interpreted as fundamentally creative within ecological models that include groups of people and partnerships. A paradigm shift is in John-Steiner's (2000) Vygotski-inspired studies on creative collaborations, where creativity is reframed as interdependent creation in distributed exchanges. Her look on small and medium-size teams of collaborators shows that creative ideas travel among individuals and milieus through distributed trajectories. Regardless of the context and the type of collaboration, partnerships of creative individuals are built on the shared engagement in active conversations among their members who are close in time and space (collaborators) but also with individuals who are distant in space and in time (role models, inspirators, teachers).

Similarly, Chadwick and de Courtivron (1993) look at the constructivist concept of *significant others* in intimate relationships drawing from creative collaborations between romantically engaged artists, and Melnick and Nevis (2003) apply Gestalt hermeneutics to the investigation

of long-term intimate relationships between artists. They emphasize the role that *form* is given in the artists' creative processes, as a sort of third dialogic partner. John-Steiner's (2000) investigation is the most complete study on artistic partnerships that contributes to a new understanding of creativity as the *interdependence* of individuals who collaborate in *distributed* creative exchanges. Sawyer (2007) coins the definition "group genius": collaborative networks of influences that need time to emerge and are based on the group's members commitment to building on each other's ideas and capacity for deep listening, suspension of judgment, and self-organizing processes. This idea is later developed in Miettinen (2006) and in Sawyer and DeZutter (2009), for whom distributed creativity emerges in "situations where collaborating groups of individuals collectively generate a shared creative product" (p. 82). This is consistent to this entry's definition of ensemble: distributed creativity can be said to be proper to ensembles, as Sawyer (2007) sustains with his concept of "group genius." Glăveanu (2014) and Clapp (2016), though, argue that group genius risks merely replacing individual genius, so they reconceptualize distributed creativity as creative interactions stretching beyond limitations of time and space. Moving from this collective, distributed, participatory creativity, it can be possible to look beyond psychological and individual-centered accounts and to engage in ethnographic and new materialistic perspectives on performance and performativity.

Creative Performance in Ensemble

Creativity is here understood as socially and culturally situated as the "interaction among *aptitude, process, and environment* by which an individual or group produces a *perceptible product* that is both novel and useful as defined within a *social context*" (Plucker et al. 2004, p. 90). However, the situatedness of creativity is here strictly entangled (Barad 2007; Haraway 2016) with the materiality of the actor's body and its "coperformativity" (Spry 2016). Different

performativity theories recognize performance “as a generative vocabulary for understanding human behavior” (Pelias 2008, p. 185) and as autonomous ways of knowing. In Pelias (2008), this has its roots in Goffman’s presentation of self (1978), Turner’s ritual (1982), and Butler’s performativity (1993). Differently from other teams, performing ensembles offer examples of creative collaborations in groups that share a bodily affective language and that work with poetic processes. This makes them a crossroad linking artistic expression, pedagogical experimentation, and activist engagement (Chemi 2018).

Individuals in teams of performers necessarily learn together: they have to tune their instruments to each other, be it the body, movement, or sound. They challenge each other to find solutions, questions, and perspectives, in order to constantly renew the repetitive element that is implicit in performance (training, rehearsal, prolonged showcasing periods). They enact social change not only by direct action on society (activism) but also by their example: by keeping the third space open as pulsating room for concrete practice. Sawyer (2007), focusing on jazz musicians and improv theatre, and Jones (2015), looking at jazz, had already touched on the ways ensembles can potentially offer knowledge on collaborative creativity. However, improvisation – in jazz or theatre ensembles – is nothing but one performative expression among a plurality of dramaturgical approaches. Burgoyne (2018) addresses this multiplicity and the explicit connection between ensemble’s processes/practices and creativity. Looking at historically defined performative practices, it is possible to single out how ensembles can establish creative environments for artists and citizens in socially sensitive areas or themes.

Theatre as community intervention (Kershaw 1992) is a frequent practice in popular theatre, political theatre, and agitprop (Barnes and Coetzee 2014), conceptually sustained by critical pedagogy (Boal 2000; Freire 1996). However, the link between creativity, performance, and activism requires more study. This is because the idea of creativity as the achievement of individual talent and genius has been influencing studies for

centuries (Kaufman and Sternberg 2010). Understanding creativity as relational and collective has been a relatively recent conquest (Craft 2001, 2005; Harris 2014). Creativity is now seen as a collective-relational phenomenon (Glăveanu 2014; Sawyer 2007; Sawyer and DeZutter 2009; Wyatt 2018), yet studies that explore the relationships between education and creativity mostly ignore the ensemble as subject of investigation and as a concept.

Applying performance and performing arts to social problems is based on the assumption that acts of *mimesis* (reproduction), *poiesis* (making), and *kinesis* (change) (Conquergood 1995) in everyday and artistic performativity can be transformative not only for the single individual but especially for individuals in co-creative relationships, for communities. The challenge, though, is methodological and ethical: how is it possible to design interventions and research methods that are postcolonial (Bhabha 1994) and that look beyond the Western claim of one-sided truths (Smith 1999)? The risk is continuing to buy into colonial discourses where public or research institutions appropriate the definition of *what is possible*, without giving local communities authority to *perform* their own identity (Smith 1999). This is telling of a more general societal tendency toward marginalization and inequality in participation in democratic structures, with the insurgence of potentially dangerous conflicts and polarizations. In other words, performance might help communities to co-create as/in ensembles and to reclaim their own future (what is possible in the future through what has been in the past).

Cultivating Ensemble Creativity

Starting from the hypothesis that the conditions for democratic principles to flourish in society are largely determined by the extent to which creative practices are established in education (paraphrasing Adams and Owens 2015), it is possible to look at performance as a tool for societal change. According to performance theorists as Schechner (2002), creative processes are fundamentally pedagogical. Schechner (2002), “defines performance

as the activity that individuals engage in when they participate in given events that are to influence other participants” (Chemi and Pompa 2017, p. 110). He is clearly inspired by Goffman’s work on the presentation of self in everyday life (1978), but extends Goffman’s interest to the pedagogical elements of creation.

In Schechner (2002), the multiple elements of performance imply learning processes: change and transformation, enquiry and research, and playfulness or play. This unfolds on several levels: the active, technical, or activist (“doing”), the poetic or expressive (“showing doing”), and the hermeneutical (“explaining showing doing”) (Schechner 2002, p. 22). In this sense, ensembles of performers offer knowledge on not only what is possible *within* creative teams but also what these groups can *make possible* outside and beyond the limits of ensembles. Neelands claims (2009) that ensembles can provide participants “with a model of democratic living” (p. 173) and that “theatre has a role to play in giving a voice to the excluded; in giving a voice to the minority; in demanding the right to speak publicly; in criticising without fear; and in questioning the borders of freedom” (Neelands 2009, p.180).

These perspectives call for a research that is performative and performance that is research: what is needed is the invention and application of (artistic and research) methodologies that privilege socially engaging, embodied, participatory, co-creative experiences. In order to design such imaginative interventions, scholars have developed hybrid forms such as performative inquiry (Pelias 2008), critical plays (Harris and Sinclair 2014), performed ethnography (Madison 2018), and performance ethnography (Denzin 2003). To address socially relevant themes, research methods must give voice to the necessity of producing analytically and critically qualitative data, reporting on human beings without reducing them to stereotypes, and generating discussions (Donmoyer and Donmoyer 2008). Original and respectful analyses are aware of the multiple presentations of selves (Goffman 1978) that are *entangled* (Barad 2007) and *diffracted* (Barad 2007; Haraway 2016), because they demand the existence of pluralities in co-creative and poetic activities. What performance and

performing arts can make possible is to shape time and space for individuals to co-create in ensembles or *as if* they were an ensemble. In these *loci*, reciprocal pedagogy (Chemi 2018) and everyday activism are the shared activities by means of which imagining alternative future is possible. Encounters become a platform to address and act on negative narratives; ensembles become laboratories for collaborative creativity.

However, performing ensembles can only contribute to the imagination of futures if affective aspects are addressed in practices and knowledge. This can be done by looking at how group flow (Sawyer 2007) and team flow (Van Hout et al. 2016) can be readdressed as co-creation (Chemi and Pompa 2017), relational creativity (Wyatt 2018), and radical generosity (Turner and Campbell 2018). In other words, a radical *affective turn* in creativity studies is needed, of the kind Turner and Campbell (2018) address by investigating the creative processes occurring within theatre ensembles, theatre laboratory, and networked theatre groups, looking at how these communities engage in radical “generosity” (p. 58).

These hybrid spaces for artistic practice and enquiry demand specific ethical considerations and guarantee the respectful inclusion of all participants. The necessary ethical measures for humanistic research and social interventions acquire an additional dimension when performance is involved: they draw from literature, where ethical and aesthetic qualities are described as indivisible, where “priority is the achievement of cathartic impact on audiences/readers as well as on actors/participants” (Chemi and Harris 2019). Resonance (Harris and Sinclair 2014), the researcher’s active role (Scott 2018) and risk of colonizing gazes (Smith 1999) are given special methodological attention and space. In this way, utopian futures acquire the tangibility of the flesh and are performed by means of material bodies in open chaotic relationship to each other.

Possible in Philosophy

Antoine Taillard

Institute of Philosophy, University of Neuchâtel,
Neuchâtel, Switzerland

Abstract

Within philosophy, the word “possible” is generally used to speak about either of the following. (1) *Possibility*: the notion that is expressed by sentences such as “It is possible that there are green cats,” “She may become the best surgeon in the city,” and “Our team can win the race.” Among the features of possibility, three are of particular interest to philosophers: it is closely related with necessity, contingency, and actuality; it is not unified, but comes in multiple varieties; it is intuitively linked to conceivability. (2) *The possible*: the target of sentences expressing a possibility, i.e., whatever is possible. Philosophical inquiry is notably interested in the existence and the nature of possible things. For those who think possible things exist, the challenge is to say how and where. For those who think possible things do not exist, the challenge is to say how sentences stating a possibility can be true.

Keywords

Possibility · Possibility-statements · Possible objects · Conceivability · Modality · Philosophy · Metaphysics

When speaking of possible in philosophy, one must be careful to distinguish between three closely related notions: possibility, possibility-statements, and the possible. Consider the following sentences: “It is possible that there are green cats,” “Space elevators are possible,” “She may become the best surgeon in the city,” “Our team can win the race.” Lexically and grammatically, it is clear that these sentences differ from each other. However, these superficial differences cannot hide a deeper unity. There is a single notion behind each of these sentences, namely *possibility*. Thus, while these sentences vary greatly in their grammatical form, they all have the following logical form:

It is possible that p

(Here and in what follows, “p” stands for some affirmative sentence; “it is possible that” is an operator ranging over this sentence.) Let us call a sentence of this form a *possibility-statement*. With possibility and possibility-statements introduced, a third notion emerges naturally: *the possible* is the target of possibility-statements, it is what sentences expressing a possibility are about; in short, it is whatever is possible.

While this entry discusses questions that occupy philosophers working on the subject of possibility, it is not written as an introduction to the philosophy of modality. Rather, the goal is to familiarize the reader with the notion of possibility as it is used within philosophy *in general*. Philosophy of modality itself is quite limited in scope. But many areas of philosophy use modal notions. Talks of possibility and necessity are extremely frequent in metaphysics. For example, these notions are central in the debate about essences, the structure of reality, the laws of nature, causality, etc. (Historically, the importance of modality for metaphysics was greater still: in the second half of the twentieth century, metaphysical debates tended to be laid in terms of possibility – with David Lewis (1973, 1986) being the most famous and enthusiastic supporter of this method. However, the turn of the millennia has seen a rise of defiance in this approach (see e.g., Fine 1994)). Outside metaphysics, possibility is an important notion too. It is sometimes used

in philosophy of action to define abilities (Brown 1988). The inquiry about permissibility in deontic logic and metaethics has been crucially influenced by the study of possibility (the classical paper here is von Wright 1951). Moreover, possibility is at the center of at least two conceptual tools that are used throughout philosophy: supervenience and arguments from possibility/conceivability.

The first section of this entry places possibility on the “map of modality,” among impossibility, necessity, contingency, and actuality. The second section highlights the important fact that there are multiple kinds of possibility. The third section asks, “what exactly is the possible?” and presents the major metaphysical debate that stems from this question. The fourth and final section discusses the relation between the possible and the conceivable.

Possibility and Other Modal Notions

What other modal notions are related to possibility? And *how* exactly are they related to possibility?

First, and most importantly, possibility is related to necessity. One can express that something is not possible by pointing to the necessity of its negation: “it is necessary that bachelors are unmarried” is logically equivalent to “it is not possible that bachelors are married.” And “it is not necessary that green cats do not exist” means that green cats are possible. More formally, necessity and possibility are interdefined in the following way (here and in what follows, “iff” abbreviates “if and only if”):

It is necessary that p iff it is not possible that non-p
It is possible that p iff it is not necessary that non-p

Since possibility and necessity are thus interdefinable, many philosophical discussions that appear to be solely about necessity are in fact relevant to the study of possibility and the possible. Philosophical investigations of possibility are more often than not studies of modality in general.

Second, possibility is related to contingency. In English, “possible” is somewhat ambiguous.

Taken in a broad sense, it is simply the opposite of impossible. In that sense, it is used merely to say something can be the case, without indicating in any way whether this thing is necessary or not. Thus, it is not only possible that all bachelors are named Sam, it is also possible (as well as necessary) that all bachelors are unmarried. But “possible” has a more restricted meaning which excludes not only impossibility, but necessity too. This is the sense at play in sentences such as “You can watch the TV if you want” or “It is possible that the valley will be flooded.”

Within philosophy, “possible” is generally used in the broader sense. Still, there is a philosophical notion that accounts for the restricted sense: contingency. It is defined from possibility in the following way:

It is contingent that p iff it is possible that p and it is possible that non-p

In other words: contingency is possibility without necessity. As is the case with the two meanings of “possible” in English, there is an asymmetry between possibility and contingency: all contingent truths are possible, but not all possible truths are contingent (since some possible truths are also necessary). This link between possibility, necessity, and contingency is summarized in Fig. 1.

Actuality is another notion found alongside possibility. In that context, to be actual is to be the case, to exist “in our world.” Thus, Barack Obama, grey cats, and the property of being red are actual. On the contrary, Sherlock Holmes, green cats, and the property of being a square circle are not. (Of course, since actuality is existence in our world, what exactly one takes to be actual depends on what one takes to exist in the first place.)

The philosophical notion of possibility is neutral about actuality. Thus, “it is possible that there

are grey cats” is a true possibility-statement and is no more problematic than “it is possible that there are green cats.” However, in English, “possible” is sometimes used to say that something can be the case *and that it is not, in fact, the case*. For example, consider “It is possible that she becomes the best surgeon” and “We could be at home right now.” What is expressed by those sentences is a *mere possibility*, defined as a non-actual possibility:

It is merely possible that p iff (i) p is possible and (ii) p is not actual

The link between actuality, possibility, and mere possibility is summarized in Fig. 2.

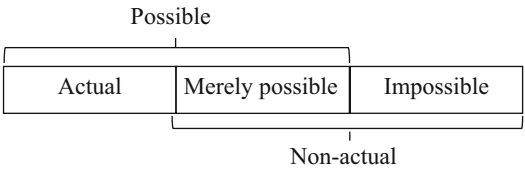

Varieties of Possibilities

Consider the following possibility-statement: “it is possible to fly from Earth to Mars in one month.” Is it true? No: there is not a single ship that will allow you to do that. Yes: it is fully compatible with the laws of nature governing space travel. Or consider: “you may eat with your hands.” Is it true? Yes, if the statement is to be interpreted as saying something about our anatomy; no (let’s assume) if it is taken to inform us about cultural permissibility.

Examples of possibility-statements that seem both true and false are easy to come by. Should we then abandon all talks of possibility as hopelessly confused or obscure? Of course not. Rather, such examples show that a single possibility-statement can be interpreted in a multitude of ways. And these various readings suggest there are various kinds of possibility. Figure 3 presents some of those kinds that are of particular philosophical interest. (This is not by any means an exhaustive list; there are many other kinds of possibility:

Possible in Philosophy, Fig. 1 Possibility, necessity, and contingency

Possible in Philosophy, Fig. 2 Possibility and actuality

Kind of possibility	It is possible...	Given...
Conceptual	that George Sand is not Amantine Dupin	<i>the concepts</i> of George Sand and Amantine Dupin
Metaphysical	that Venus is the planet closest to the Sun	<i>the nature</i> of Venus
Nomological	for a ship to reach Alpha Centauri in less than five years	<i>the laws</i> of the universe
Normative	for you to walk on the lawn	<i>the norms</i>
Epistemic	that Sam is the murderer	<i>the evidences</i> available to the agent

Possible in Philosophy, Fig. 3 The third column indicates the type of truths relevant to determine the kind of possibility

mathematical, biological, technological, sociological, historical, etc.)

The kind of possibility expressed by a possibility-statement is determined by the set of truths compatible with this statement. For example, while the set of truths about the nature of Venus plausibly contains “Venus is a celestial body,” “Venus is a terrestrial planet,” and many others, it does *not* contain “Venus is the second planet closest to the Sun.” (The nature of Venus would not change should Mercury disappear.) Thus, “it is possible that Venus is the planet closest to the Sun” is compatible with truths about the nature of Venus and expresses a metaphysical possibility.

How are the various kinds of possibility related to each other? To answer, notice first that at least some possibility-statements express more than one kind of possibility. In other words, some possibilities belong to more than one kind. For example, not only is it a metaphysical possibility that Venus is the planet closest to the Sun, it is also a conceptual one: the concept of Venus does contain the concept of the second planet closest to the Sun. (By contrast, notice how the concept of bachelor seems to contain the concept of unmarried.)

From this observation, one is naturally led to wonder about the *hierarchical structure* of these kinds. Are some kinds of possibility merely species of other kinds, in the sense that any statement expressing a possibility of the first kind also

expresses a possibility of the second kind (but not vice versa)? For example, are all nomological possibilities also metaphysical possibilities? And further: is there a fundamental kind of possibility? Is there a single (philosophically interesting) kind of possibility, in terms of which all the others can be defined?

In many instances, the reduction of one kind of possibility to another is problematic. Take, for example, the metaphysical/conceptual case. As Kripke (1980) famously argued, some conceptual possibilities are not metaphysical. While “George Sand is not Amantine Dupin” is a conceptual possibility, it is not a metaphysical one: indeed, the names “George Sand” and “Amantine Dupin” denote one and the same thing and it is metaphysically impossible that something is different from itself. And there are also metaphysical possibilities that are not conceptual ones. Let “HiTo” be the name of the highest tower on Earth. This stipulation makes it such that the concept of HiTo contains the concept of the highest tower on Earth. So, it is conceptually impossible that HiTo is not the highest tower on Earth. However, it seems to be a metaphysical possibility: it is not in the nature of the object currently denoted by “HiTo” (the Burj Khalifa in Dubai) to be the highest tower on Earth. Thus, while the set of conceptual possibilities and the set of metaphysical possibilities overlap, neither is a subset of the other.

To say that reduction of one kind of possibility to another is problematic is not to say that it cannot be achieved. For example, there are no major difficulties in reducing nomological possibilities to metaphysical possibilities. (Interestingly, the reduction of nomological *necessities* – laws of nature – to metaphysical necessities is much more controversial. See e.g., Ellis 1999; Shoemaker 1998) But the general reduction of all varieties of possibility to a single fundamental kind seems seriously compromised.

Target of Possibility: Truths and Objects

The possible is the target of possibility-statements; it is the thing such a statement is about, the thing it ascribes possibility to. What is this thing, then?

A first suggestion: possible things are affirmative sentences. Thus, “it is possible that there are green cats” says the sentence “there are green cats” is possible. This suggestion has the advantage to strictly follow the logical form of possibility-statements. As we saw, the operator “it is possible that” ranges over *p*, an affirmative sentence. However, it is not very clear what it means for an affirmative sentence to be possible. Clearly, it does not mean it is possible the sentence *exists*. The sentence “There are married bachelors” exists, but it is obviously impossible that there are married bachelors.

A better suggestion: a possibility-statement “it is possible that *p*” is not concerned about whether *p* exists, but about whether *p* is true. Thus, “Possibly, there are green cats” does not mean it is possible that the sentence “there are green cats” exists. Rather, it means the sentence is possibly true. According to this view, the target of a possibility-statement “it is possible that *p*” is *the truth value* of *p*. If it is possible that *p* is true, then the possibility-statement itself is true. If it is not possible that *p* is true (e.g., if *p* is self-contradictory, such as “there are married bachelors”), then the possibility-statement itself is false.

However, this answer raises two worries. First, one can legitimately wonder what it is exactly for a sentence to be possibly true. “Some bachelors

live on Mars” is false. So is “some bachelors are married.” But the former is (metaphysically) possibly true, while the latter is not. How come? What is the criterion for deciding whether it is possible that *p* is true? Second, possibility-statements are not merely about the possible truth value of sentences. Intuitively, “it is possible to reach Mars in one year” says something about how the world is, about the current technology or the laws of nature. Thus, possibility-statements are not (solely) about possible truths, but about possible things in the world, about possible *objects*.

This last point leads to a third suggestion: the target of a possibility-statement “it is possible that *p*” is not (merely) the truth value of *p*, but whatever object is picked out by *p*. “Possibly there are green cats” does not merely say that “there are green cats” is a possible truth. It says that green cats are possible objects. This suggestion also helps with the other problem raised by the previous account. Indeed, we now have a simple criterion for determining whether an affirmative sentence is possibly true: *p* is possibly true iff there is a possible object corresponding to *p*. “There are green cats” is possibly true iff green cats are *possible objects*. “Venus is the planet closest to the Sun” is possibly true iff it is a *possible fact* that Venus is the planet closest to the Sun. This has the advantage to mirror the standard criterion for truth in general: *p* is true iff there is an object corresponding to *p*. “There are grey cats” is true iff there are grey cats. “Mercury is the planet closest to the Sun” is true iff it is a fact that Mercury is closest to the Sun. Thus, possible truths are only a species of truths in general and require no special treatment.

Since possibility is neutral about actuality (see section “[Possibility and Other Modal Notions](#)”), at least some possibly true sentences are also actually true. For those, there are no particular problems with the criterion just suggested. “There are grey cats” is possibly true, iff there are possible objects that are grey cats. And sure enough, there *are* such possible objects: the *actual* grey cats.

But what about *mere* possibilities, possible truths that are not actual truths? Given the above criterion, since “there are green cats” is possibly

true, there are (possible) green cats. But obviously, no actual object is a green cat. Where do we go from there, then? How to save the suggested criterion for determining which sentences are possibly true? This is one of the main questions in the philosophy of modality.

In contemporary literature, there are two main views about merely possible objects. On one side, we have possibilism, the thesis that merely possible objects are real, in exactly the same way that actual objects are. According to this view, there *are* green cats as well as grey ones. Only, the formers do not exist in the same “modal space” as the latters: they do not exist in our world, but in another possible world.

The most famous version of possibilism is Lewis’ modal realism (1986). Lewis thinks of possible worlds as maximally inclusive regions of space-time, that is, spatiotemporal wholes. In his view (1970), “actual” is nothing more than an indexical term useful to speak of our possible world, as “here” is useful to speak of the location we are at. And as there is nothing special about the location denoted by “here,” there is nothing special about the actual world.

For general sentences such as “there are green cats,” modal realism allows to keep the criterion suggested above untouched. The sentence is possibly true, iff some possible worlds include green cats. (And the sentence is *actually* true iff one of these worlds is the actual one.)

However, for singular sentences – that is, sentences about a specific individual, such as “Venus is the planet closest to its star” – more needs to be said. Indeed, “Venus” denotes an object in *our* world, not an object in another possible world. Thus, there is no world where it is a fact that Venus is the planet closest to its star. And so, modal realism cannot account for the sentence being possibly true. To answer this problem, Lewis developed a counterpart theory (1968). While only the actual world includes Venus, some other possible worlds include *counterparts* of Venus, that is, objects qualitatively similar to Venus, objects sharing some properties with Venus (e.g., the property of *being a terrestrial planet*, of *having a periaapsis of 0.7 AU*, etc.).

The possibility-statement “Possibly, Venus is the planet closest to its star” is then analyzed as “there is some *counterpart* of Venus such that this counterpart is the planet closest to its star.”

Another version of possibilism is modal dimensionalism (Yagisawa 2010; see also Graham 2015). Rather than accepting multiple spatiotemporally extended worlds, modal dimensionalism accepts only one world that is both spatiotemporally and modally extended. My cat is playing in some place (i.e., at some spatial index) and eating at another. My cat is asleep at some instant (i.e., at some temporal index) and awake at another. Similarly, my cat is grey at some modal index and green at another. Contrary to Lewisian realism, modal dimensionalism does not require a counterpart theory. “It is possible that my cat is green” is not made true by some green *counterpart* of my cat living in a different possible world; rather, it is made true by the existence of *my* cat at the modal indices where it is green.

The other (and much more popular) view about merely possible objects is actualism, the thesis that everything – in particular every possible object – is actual. According to actualism, then, merely possible objects such as green cats do not exist. While actualism does not come with the heavy ontological cost of possibilism, it must face the problem of providing a criterion for merely possible truths such as “there are green cats.”

One answer to this problem is given by ersatzism. In lieu of merely possible objects, ersatzists admit only actual representations of such objects. Green cats do not exist, but some actual representations of green cats do. The various ersatzists’ views differ on what exactly these representations are taken to be. Notable suggestions include sentences (Carnap 1947, esp. sec. 2) and meanings of sentences, that is, propositions (Adams 1974). A possible world can then be defined as a maximally consistent set of representations: a set of representations whose members would all be correct were the represented objects to exist, and to which no member can be added without creating a pair of contradictory

representations. From there, the following account of possible truths is given: “there are green cats” is possibly true iff there is a possible world that contains a representation of green cats. Two points are worth mentioning here. First, ersatzism is not a reductive theory of possibility. Indeed, as introduced here, consistency is a modal notion. Second, according to ersatzism, the criterion for merely possible truths do not mirror the standard criterion for truths in general.

Besides ersatzism, there are other ways one can provide a criterion for merely possible truths without committing themselves to the existence of non-actual objects. One can argue green cats and the fact that Venus is the planet closest to the Sun *are* actual objects, although not concrete ones. This view is known as new actualism (Linsky and Zalta 1994; Williamson 1998). As for possibilism, it has the advantage to straightforwardly preserve the criterion for possible truth. It must, however, face the suspicion that the difference between actual non-concrete objects and merely possible objects is a difference in name only.

An actualist may also go with necessitism, the thesis that necessarily, all truths are necessary, that is, necessarily, there are no mere possible truths. In this form, the view has no contemporary supporters (but see Williamson 2013 for a discussion). While it avoids postulating possible or mysterious non-concrete objects, it has at least two major issues: first, it is very implausible that *all* possibility-statements are false; second, it is unable to account for the intuitive distinction in truth value between sentences that are possibly true and sentences that are not possibly true (e.g., “there are some married bachelors”). Still, necessitism is a real alternative to the actualist and maybe a working theory can be extracted from it.

Possibility and Conceivability

Intuitively, possibility and possible objects are related to fictions, make-believe, imagination, and the like. In philosophy, this intuition is most

often laid in terms of the link between possibility and *conceivability*.

Defining conceivability is obviously the major issue in this debate. Here, the following characterization of what it is for something to be conceivable will suffice. A concept is broadly understood as a mental representation: my concept of Mars represents Mars in the same way as the word “Mars” and a picture of Mars do. To conceive something is to have (or to form) the concept of this thing. “To conceive” is thus a generic term denoting a variety of activities, such as to entertain the thought of, to imagine, to hypothesize, etc. (Gendler and Hawthorne 2002, p. 7 discuss other examples.) Something is then said to be conceivable iff it can be conceived, iff it is possible to have a concept of it.

When investigating the link between conceivability and possibility, it is important to specify which *kind* of possibility is at play (section “[Varieties of Possibilities](#)”). For example, it is obvious that nomological or normative possibilities are neither identical to nor entailed by conceivability. On the contrary, it seems to follow from the definition of being conceivable that it is identical to being conceptually possible. Arguably, “it is possible to have the concept of Venus as the planet closest to the Sun” is synonymous with “it is possible that Venus is the planet closest to the Sun *given the concept of Venus*.” Here, the discussion will focus on *metaphysical* possibility. Indeed, the link between conceivability and metaphysical possibility is generally the one that attracts the most interest from philosophers. A reason for that is that one would like to use so-called arguments of conceivability: to support claims about the nature of things from claims about what things are conceivable (see e.g., Chalmers 2003, p. 106). Such arguments require the relation between conceivability and metaphysical possibility to be one of two kinds: identity or entailment.

Is conceivability *identical to* metaphysical possibility? Is being conceivable the same as being metaphysically possible? No. To see why, note first that conceivability is a modal notion: being possible figures in the definition of being conceivable. Conceivability-statements can thus

be transformed into possibility-statements. “It is conceivable that Venus is the planet closest to the Sun” is equivalent to “it is possible to have the concept of Venus as the planet closest to the Sun.” But the possibility behind that last statement is clearly not the same as the possibility behind “It is possible that Venus is the planet closest to the Sun given the nature of Venus.” The latter statement is about the nature of Venus while the former is about the nature of the *concept* of Venus (and maybe the nature of the entity having the concept). Also, while the second statement expresses a mere possibility, the possibility expressed by the first statement is actual.

Does conceivability *entail* metaphysical possibility? Are all conceivable things metaphysically possible? Here too, the answer seems to be negative. In section “[Varieties of Possibilities](#)”, we saw that at least some conceptual possibilities (“Amantine Dupin is not George Sand”) were metaphysical impossibilities. If we add the plausible assumption that conceivability just is conceptual possibility, we get the consequence that some conceivable things (the state of affairs *Amantine Dupin being different from George Sand*) are not metaphysically possible.

Another often-cited counter example to the thesis that conceivability entails metaphysical possibility builds on the unproven mathematical affirmation known as the Goldbach conjecture: “every even integer greater than 2 can be expressed as the sum of two primes.” It is conceivable the conjecture is false and it is conceivable the negation of the conjecture is false. But mathematical affirmations such as the conjecture and its negation are widely taken to be necessarily true, if true at all. Thus, whether the conjecture is true or its negation is true, we have conceivability without possibility.

There are, however, various proposals in order to avoid these counterexamples. The main strategy consists of showing there is a better definition of conceivability, one under which the counterexamples are not in fact cases of conceivability. Building on Descartes’ argument for dualism, Van Cleve (1983, p. 37) defines what he calls *strong conceivability*: something is conceivable for a subject iff that subject sees (perceives clearly

and distinctly in his mind) that *p* is possible. This definition avoids the counterexample just mentioned, since there is no such clear and distinct perception in those cases. Yablo (1993, sec. X) makes a similar suggestion: it is conceivable that *p* if I can imagine a world (or situation) in which *p* is true. Thus, it is not the case that “Amantine Dupin is not George Sand” is conceivable, since the names “Amantine Dupin” and “George Sand” denote one and the same person. (A similar proposal is made by Chalmers 2002) Whether these solutions really succeed in establishing the entailment from conceivability to metaphysical possibility is yet to be determined.

Conclusion

While possibility and possible objects have been thoroughly explored by philosophers, these notions are still the target of philosophical inquiry. This is not to say that there are no consensual views about them. In particular, the link between possibility and the other modal notions of necessity, contingency, and actuality is largely admitted in the philosophical literature. But important points for the philosophy of modality are still debated, notably the nature of possible objects and the link between the varieties of possibility. These being distinctly philosophical questions, it is not clear if and how the special sciences can help here. Whatever is the case, it is worth keeping these problems in mind. Indeed, modal notions are so fundamental and so common that one will undoubtedly meet and use them – especially if one is interested in counterfactual beliefs, imagination, pretense, and the like.

Definition

Photography is a form of expression. It uses images to communicate. Previously called *heliography*, *daguerreotype*, or *calotype*, the process of capturing images in a permanent way was assigned the term *photography* by Sir John F. W. Herschel in 1839 (Newhall 2009, p. 21). The etymology of *photography* comes from the ancient Greek and it is composed by two words: *photos* and *graphein*. *Photos* literally means “of the light.” *Graphein* means writing. Photography is the writing of the light. Every time we take a photograph, we are “writing” a message and it is important that we know how to ‘write’ this message to properly communicate. Photography uses a complex system of signs in the same way as written language does. The complexity of this system of communication arises from the way that the used signs can be misinterpreted and create different associations for each viewer/reader. This is one of the reasons why photography as a visual language has been studied by semiologists (Barthes 1977; Berger 2014; Joly 2015; Lester 2014; Rose 2001).

In this sense, as a communication system, photography makes communication possible between human beings. It makes this communication possible across spatial and temporal distance.

Introduction

A black wooden case (7 × 5.5 cm) covered by decorated leather (Fig. 1): this is a daguerreotype from the middle years of the nineteenth century.

Possible in Photography, Fig. 1 Unknown. *Portrait of an unknown young man*. 1850 c. Daguerreotype. (Source: Arese Visconti private collection)

Once opened, protected by felt and behind a glass, we discover a shiny, reflective portrait of a man mounted in a golden frame. This portrait was taken on a silver plate. A man in his thirties stares at us. He wears a white shirt with a bow tie, a waistcoat, and a jacket. With a long goatee beard and hair which covers his ears, he looks straight into the camera. The lack of expression enhances what Walter Benjamin (1935) called the aura, the unique phenomenon of the distance. It is a temporal distance. Staring at us with this neutral expression from another century, this man establishes a dialogue with us. Who is he? What was his job? Which were his fears, his goals, his achievements in life? What did he do right after this photographic session? Did he go back home? Did he have an appointment? A photographic portrait of an ordinary man makes possible an improbable, but intense, dialogue through centuries. Can portrait photography produce some sort of immortality for humans?

Photographic portraiture became a mass phenomenon with the official presentation of the daguerreotype at the Académie de France in

1839, (Sorlin 2001, p. 21). Until the middle years of the nineteenth century, only kings and aristocrats could afford to have a portrait painted and even in that case it was an idealized representation of reality (Burke 2001, p. 22). Photography made the representation of the self-accessible to a large number of people. If by the democratization of photographic portraiture, we mean the financial and technical accessibility of the mass to the medium, what are the pivotal moments in the history of photography which marked this phenomenon? Through a reflection on the value and characteristics of portrait photography on daguerreotypes, on *cartes de visite*, on snapshots taken with Kodak Brownie cameras and on smartphones selfies, this chapter will explore whether or not the value of photographic portrait for the masses has changed and the possibility of becoming somehow immortal (being *immortalized*) through a photographic portrait has been maintained through centuries. While this point could be seen only as a positive aspect generated by technological innovation, we will see that there is also a negative impact on society.

Daguerreotype: A Mirror with a Memory

Developed in collaboration with Nicéphore Niépce, the Daguerreotype process was presented for the first time by Louis Jacques Mandé Daguerre on August the 15th 1839 at the Academy of Sciences and at the Academy of Fine Arts in Paris. The rights to the invention were bought by the French government which made them open to the public. In the first years after the official presentation, the main themes represented on the daguerreotypes were still life and architecture (Newhall 2009, p. 19). The exposure times were too long to allow portraits. Subsequent technical improvements shortened exposure times from several minutes to few seconds and so, by 1841, photographic portraits were common. Photographic studios offering portraits on daguerreotypes opened almost everywhere in the Western world (Newhall 2009, p. 30). The vast majority of daguerreotypes still existing today are portraits and were taken in studios fully equipped for that purpose. It is likely that four out of five daguerreotypes in the mid nineteenth century were portraits (Sorlin 2001, p. 32). Face and human body became the main subjects of a different figurative art fully based on photography. They are very detailed in their realistic representation.¹ They offered a contrast with the paintings that had gone before; while photographic images portrayed mortal human beings with their imperfections and defects, paintings could translate an interpreted reality. Painters were able to disguise the deformities and enhance the postures and gestures of the sitters and provide them with accessories and objects to deliver a message (Burke 2001, pp. 25–26). These aspects had a meaning

which usually supported the kings, queens, or aristocrats' portrayed desires of self-representation. A painted portrait of the nineteenth century was not the equivalent of a realistic image, but was rather the result of the collaboration of the artist and the sitter and referred to by Goffman (1969) as meaning of the presentation of the self. In the production of portraits with the new photographic medium, new iconographic conventions were introduced. Daguerreotypes followed those ones of coeval very popular miniatures: sitters were mostly portrayed against a neutral background, with a diffused light usually coming from the ceiling; because of the long exposure time and the risk of blurring, sitters were asked not to smile and to look straight forward into the camera. The photographer was, of course, the intermediary between the sitter and the viewer, but it is the gaze offered by the sitter to the lens which generates that direct connection with the viewer even after centuries. Still today, when looking at a daguerreotype portrait, we feel that we are facing a presence. Walter Benjamin (2015, p. 29) in his "Little History of Photography" argues that these presences became distinct and had an aura because of the reserve of the bourgeois sitters, with genuine innocence in front of the camera (they didn't know what that was), and the contrast tones and long exposures (so that the subjects had to hold the same expression for a long time).²

Daguerreotypes had very sharp details. They also inverted the image (in the same way we see ourselves on a mirror) and represented a mass phenomenon which needed an intermediary (a photographer) to be produced. Every daguerreotype was different, unique and not reproduceable. The invention of the paper negative and, then, of the negative on glass favored the multiple reproduction of the same shot and signed another key moment in the history of photography. The *carte de visite* was one of the products that were promoted after this technical innovation.

¹ Description of the qualities of a daguerreotype by Sir John F. W. Herschel to William Henry Fox Talbot, May 9th 1839: 'It is hardly too much to call them miraculous. Certainly, they surpass anything I could have conceived as within the bounds of reasonable expectation. The most elaborate engraving falls far short of the riches and delicateness of execution, every gradation of light and shade is given with a softness and fidelity which sets all painting at an immeasurable distance' (Newhall 2009, p. 21).

² These elements will return in contemporary photographers like Avedon, Hanzlova, Dijkstra (see Stallabrass 2007).

The Facebook of the 1860s: la Carte de Visite

In the middle of the nineteenth century, 8–12 lens photographic cameras were used to reproduce several images on one single negative plate. These small images were cut and then mounted on cardboard (Fig. 2). Many copies from the same negatives could be reproduced. In 1854, André Adolphe-Eugène Disderi (1819–1889) patented the carte-de-visite system in France and standardized the photograph size mounted on card stock 6×10 cm. Motion was not a problem in this kind of photography as most portraiture took place indoor in a controlled environment with exposures no longer than 15 s.

These photographs were printed directly from the negative and, therefore, not enlarged. The

resultant image was detailed, but not as crisp as a daguerreotype. The use of the negative allowed straight rather than inverted images. The cost of the process was acceptable and the relatively small size of the final product supported the spread of it. People started to collect portraits and have them in their pockets all the time (in the same way we do today with our phones...). Historian Ronald S. Coddington (2016) states that the carte de visite developed into a social media phenomenon, and defined its invention as the greatest since the birth of photography: small, light, and portable, the carte de visite allowed to write on it the details of the person pictured. It represented one more step towards the democratization of photography and was an inexpensive form of social medium accessible to anyone. In the 1862 *London Review* (Coddington 2016), one could read “here there is no barrier of rank, no chancel end; the poorest owns his three inches of cardboard, and the richest can claim no more. When they serve as pegs on which to hang our knowledge and sentiment, our memories and associations, they may be the highest use.” Cartes de visite were a large mass phenomenon which still needed an intermediary (photographer) to realize the final print.

‘You Press the Button, We Do the Rest:’ the Kodak Brownie Snapshot

This is a Kodak circular snapshot photograph of two young children walking down a road, taken by an unknown photographer in the United Kingdom in 1890 c. (Fig. 3). The photograph was taken with a Kodak Brownie camera: a simple, leather-covered wooden box designed for amateur use, which produced circular snapshots two and a half inches in diameter. Invented by George Eastman in 1888, the Brownie camera was sold preloaded with film, and when the whole film had been exposed the camera was sent back to Kodak who developed it, returning the prints and the reloaded camera. “You press the button, we do the rest” stated the advertisement of the Brownie Camera. This process represented another mass phenomenon in the history of photography marked by its easy access to anyone. Despite of the disadvantage of less precise details than a

 Library)

daguerreotype, the Kodak Brownie snapshot had the advantage of not needing an intermediary to press the shutter. There was no need of particular technical knowledge and for this reason it represented another milestone for the mass diffusion of portrait photography. After the expansion of the Kodak Company and the development of the amateur photography market from the end of the nineteenth century, there have been other important technological innovations which contributed to the democratization of the medium (see the invention of the Polaroid system, the disposable cameras, and, obviously, the birth and growth of digital photography). However, it is particularly after the invention of the first smartphone with a camera,³ the broader accessibility of photographic practices to masses, and the introduction of social media platforms that

the diffusion and publication of self-portraits have impressively grown. These aspects made possible the process of democratization of portrait photography and added strong elements for reflection on the representation of the self (Fig. 4).

Selfies: The Online Social Shop-Window

Between March and May 2020, during the lockdown period against the spread of the COVID-19, on the online version of the newspaper *La Repubblica* the famous photographer Oliviero Toscani promoted the initiative “A selfie for Oliviero Toscani. Let’s become reporters of ourselves to narrate our lives during the age of Coronavirus.” Without having any specific technical knowledge, thousands of people sent their selfies to the newspaper and created a large online community. This phenomenon once again highlights the typical characteristics of the last frontier of portrait photography.

³In 1999 Kyocera Visual Phone VP-210 was the first smartphone to incorporate a 110,000-pixel frontal camera (Yegulalp 2012).

Possible in Photography, Fig. 4 Screenshot of the page. https://www.repubblica.it/cronaca/2020/03/31/news/coronavirus_selfie_toscani-252823917/. (Accessed April 15th 2020)

Merriam-Webster dictionary (Selfie 2020) defines the term “selfie” as “an image that includes oneself (often with another person or as part of a group) and is taken by oneself using a digital camera especially for posing on social networks.” Selfies have some similarities with the previous forms of portrait photography, but add new elements as well.

In common with the previous forms of portrait photography (daguerreotype, carte de visite and Brownie Kodak snapshots), selfies involve the

democratization of the medium: anyone with a basic knowledge of how to use a smartphone is capable of taking self-portraits (selfies). Like the daguerreotype, the carte de visite and the Kodak Brownie snapshot, selfies are taken to express the same desire of recording memories. Despite of all these similarities with the previous forms of portrait photography, selfies do not need an intermediate (photographer or lab to develop pictures): we are the first users (Bate 2016; Brus 2017). You see yourself and you choose when to shoot. This is the first main difference of this form of photographic portrait when compared with the previous ones. Selfies are more interactive with the portrayed person. Kodak snapshots had a “personal agency and were a cultural ritual” (Brus 2017, p. 88). They made possible the freedom of self-expression and familiar private life. Like the snapshot, selfies show what we are and where we are. This is the main point of my argument: selfies are the latest element of the process of democratization of portrait photography of the first 20 years of the twenty-first century. They reinforce the dominant position of the sitter as being simultaneously the author and the user. Technological innovation in photography has made possible for everyone to be able to take selfies independently without the help of any intermediary and to make public our faces. Selfies are not individual, rather social acts and can be seen as part of the *Identity Work* theory (Snow and Anderson 1987): we build our identity every day through the way we dress, speak, move. Taking selfies becomes part of the contemporary action of building our identity. As argued by David Bate (2016, p. 37), with selfies “the event is already mediated into an image even before it is perceived.” Since we are looking at a screen, Bate explains that emotions and *experiences are already mediated as images*. In the selfie, face and frontality prevail. The face could be considered the place where experiential and communicative functions are concentrated (AA 2017). As a flat surface on which other organs work (eyes, mouth, muscles, etc.), the face is where movements (through muscles) show passions and emotions. It is unclear and difficult to define the notion of face. It involves expression, recognition, frontality, and look (AA 2017) which are all concerned with

communication. The face is the first of several planes (expressions) which confront you with the others. It is, then, possible to say that the face has multiple expressions, but only one is frozen in a selfie posted on social media. When a selfie is taken, an act of performance is happening. People perform in front of the lens. All the process is connected with the etymological meaning of “face:” *facere*. *Facere* comes from Latin and it means “to make.” “To make” implies the sense of producing something including the act of performing. “The performative aesthetics animate our everyday activities” (Bate 2016, p. 93). Portraits have always been social performances, a social illusion (Burke 2001), but selfies today don’t have the interpreter. As painters in the past interpreted their subjects according to the coeval society (historical moment), today we take our selfies to transmit our image to the social context, and we do not need an interpreter for doing this. We are our own interpreters. It is a physical extension/experience of our body (we see in the selfies that the photographic device is attached to the body of the person portrayed by the shape of the shoulder and the position of the arm). Selfies and their digital world are more complex than a simple portrait. The person portrayed is an agent. Being *homo faber*, he or she become its own *deus ex machina*. As stated by Italian sociologist Vanni Codeluppi (2007), digital photography and its applications involve the individual under several points of view. Selfies are a physical experience. The photographic device is part of the body, part of the physical identity.

Human society has developed the concept of the shop window and, therefore, individuals today adopt this model in its virtual form, an exhibition model for valorization. A selfie is not only the act of producing a self-portrait, but it is taken with the idea of being shared on the web. The moment of its production (the decision of “pressing” the “shutter”) implies already the web-sharing process. The online social shop-window is a concept developed by Codeluppi (2007). Shop windows make useless the physical presence of the owner. They change the relationship between the seller and the client. They make the shop “un-personalized.” Shop windows are also a place of vision: it is like a stage on which a show is going on. It is the

place of self-exhibition. From the eighteenth century (when they were initially invented), the idea of the shop window has had social implications up to the point that we have been influenced in the perception of the self in relation with the others and, in this regard, the exhibition of our private life. This process of becoming objects exhibited on an online shop window corresponds to a sense of alienation, solitude of humans. We decide how we want to appear and create an *avatar*. Upon the creation of this *avatar* and the publication of the image on social media (necessary condition for the existence and justification of the selfie), we become part of a twenty-first century imagined *online* community (Anderson 1991) in the process of self-recognition as a group. Society and technological innovation, once again, are interwoven. This point recalls sociologist Latour’s (1990) reflections on society and technology and their relation to power and domination. His theory (Latour 2005) acknowledges that society is assembled by interactions of human and non-human actors (like smartphones, selfies, and online platforms in this case). Digital production and its actors (human and non-human) initiate complex and dynamic phenomena which involve social interaction and political agenda. The high democratization of portrait photography due to the introduction of smartphones with cameras and social media platforms opens a new chapter of reflections on how this could be seen as positive social progress for the technical development and accessibility, but also its negative implications. Beyond the idea of rhetoric of progress, we must not limit our analysis to simply describe the use of the medium and understand the social implications of technological innovation.

Does photography make some things possible that are actually harmful? Is taking and posting selfies on social networks only a positive and worthwhile activity? The answer is that the democratization of the medium with the broad accessibility to the masses brings with it also negative consequences related to two aspects in particular. Research shows that individuals are psychologically impacted and that there are issues related to the possible abuse of privacy of the online population. As far as the first point is

concerned, studies (Katz and Crocker 2015; Mills et al. 2018; Scott et al. 2018) state that selfies can cause addiction in particular on young users. Often linked to narcissism (Katz and Crocker 2015, p. 1861, 1865), selfies can have negative effects on mood and body image of young women (Mills et al. 2018). Defined as a self-presentation strategy, selfies are pointed as the cause of “changes to mood and feelings of physical attractiveness” (Mills et al. 2018, p. 86). Lastly, it has been highlighted that while these technical innovations support the development of new forms of oral, verbal, and visual communication (Katz and Crocker 2015, p. 1871), they can be detrimental for the level of quality in relationships and involve a decrease of intimacy and support (Houghton et al. 2013).

Two billion photos were estimated to be uploaded on Facebook every month (Stefanone et al. 2011) already in 2011. These numbers have grown: one trillion photos were taken and posted on social media in 2018 (Suciu 2019). Photographs and photographic portraits can turn into a big business. Since 2014, Facebook started using the face recognition technology called “Deep Face,” an algorithm able to identify a face in a crowd with 97.35% accuracy (Taigman et al. 2014). Facial recognition is also used to unlock smartphones. Where is this information going? Are we sure that our faces are not recorded? Selfies can provide invaluable information for commercial or population control purposes. The idea of using portrait photography for police control was already introduced by Alphonse Bertillon (the so-called *bertillonage*) at the end of the nineteenth century (Sekula 1986), but technology applied to modern portrait photography, with location information and facial recognition, expands the possibility of tracking people on a global dimension. Selfies provide an incredible amount of visual information of people. How are our online portrait used and by whom? This is the other side of the possible in photography. Next to the positive aspects listed before, like the wide accessibility to the medium and its democratization, it is important to acknowledge the “dark” side of it with negative consequences on the private and public scale for the individual.

Conclusions

Photographic portraits of ordinary people make an intense communication possible and this communication is in the foundation of the history of photography. Daguerreotypes, cartes de visite, Kodak Brownie snapshots, and modern selfies have contributed to the increasing democratization of photography. Daguerreotypes were characterized by an incredibly sharp mirrored image, which needed the inclusion of an intermediary to be produced. Cartes de visite were not enlarged, therefore quite sharp and still needed an intermediary. The Kodak Brownie snapshots had the same characteristics, but with a lower quality. In the same way as daguerreotypes, carte de visite, and snapshots, selfies have led to the mass diffusion and democratization of the medium, but in all the previous forms of photographic portraiture, technical knowledge was a *condicio sine qua non*. Selfies are accessible and free and raise questions of self-representation, society, community, and identity. They all make possible to represent the self and make us somehow immortal. Selfies also introduce the new concept of web sharing and publication. The image will be used not only in a private context and made public. The introduction of new technologies in portrait photography changed the possible and alongside the positives of democratization probably redirected its applications towards harmful consequences for the modern user. Research shows that there is a negative impact on the psychological sphere of individuals and that there is a high risk of privacy control. What seems to be a funny amusement (shooting a selfie) can actually be transformed in a tool related to power and domination. Are we going to be or are we already part of the “selfie sapiens”⁴ species?

⁴“Selfie Sapiens” (TedX Talks 2016) is a concept introduced by Hollywood producer Niels Juul. In his TedX Talk, Juul stresses the idea that, with the evolution of technology, humans increasingly depend on the use of social media. The young generation, he states, is not able to reflect on the consequences the uncontrolled production of selfies can imply.

Possible in Psychology

Vlad P. Glăveanu

School of Psychology, Dublin City University,
Dublin, Ireland

Centre for the Science of Learning and
Technology, University of Bergen, Bergen,
Norway

Abstract

As the science that studies the mental functioning, behavioral expression and contextual embeddedness of human beings, psychology is well equipped to deal with questions related to the possible and, more specifically, to human possibility (and impossibility). This entry examines seven main branches – general psychology, developmental psychology, individual differences, social psychology, clinical psychology, organizational psychology, and educational psychology – and focuses on: a) how the notion of the possible and associated concepts are employed by key theories; b) what the consequences of focusing on human possibility – and its inter-play with impossibility – are for our understanding of psychology’s sub-disciplines; and c) what new questions we could raise and studies we could conduct that would place psychology at the heart of the emerging field of possibility studies. The aim is to offer a prospective look at old psychological questions, one that integrates agency, indeterminacy, multiplicity, and the future into our concerns, research, and practice.

Definition

As the science that studies the mental functioning, behavioral expression, and contextual

embeddedness of human beings, psychology is well equipped to deal with questions related to the possible and, more specifically, to human possibility (and impossibility). And yet, these notions rarely feature within a classic psychological vocabulary and are certainly not often found in textbook, handbooks, or regular volumes (for a marked exception, see Martin and Sugarman 1999). To be fair, the language used by psychologists does refer back to the possible or, rather, to various dimensions or aspects of it, as many entries in this encyclopedia amply demonstrate. From curiosity and imagination to counterfactual thinking, hope, and innovation, human possibility is studied in psychology at an emotional, cognitive, and motivational level in the case of individuals, groups, and even society. However, we are still to fully engage, as a community, with the possible as an authentic field of inquiry for the psychological and behavioral sciences (for a call, see Glăveanu 2018).

There are a number of reasons for this state of conceptual omission. First of all, the notion of the possible might seem rather abstract and become easily relegated to the fields of philosophy and logic. Second, the complexity of the topic makes it hard to “locate” it within any of the traditional branches of the discipline (even if, as we will see in this entry, all its main branches do have something relevant to tell us about human possibility). In an era of increased specialization, the generalist and interdisciplinary approach required by possibility studies can be exciting for some psychologists but challenging for others. Thirdly, and most importantly, while engagement with the possible shapes our life course and defines our existence as human beings, the focus for many in psychology, historically and today, has been rather on impossibilities or the different kinds of determinism – biological, psychological, social – that reduce agency, choice, and alternatives (Immergluck 1964). In other words, the limits and constraints placed on human potentiality have always been given more attention, empirical and theoretical, than its triggers, processes, and consequences. This state of affairs has many roots, from an implicit assumption that living in society necessarily means “taming” an individual’s possibility to act as he or she wishes, to the convenience with which problems and obstacles on the path of such

possibility can be studied in an analytical manner. In any case, the impact on the discipline is the same: a relative lack of interest for the broad topic of the possible and a consistent focus on the impossibilities that condition, if not determine, who we are and who we become.

Of course, as this entry will demonstrate, there are many exceptions to this general observation, and they can be found in all the traditional areas of psychological science. As follows, I will consider seven such domains, each one containing a variety of perspectives or approaches, and focus on: (a) how the notion of the possible, even when not used directly, is embedded within key theories or studies; (b) what the consequences of focusing on human possibility – and its interplay with impossibility – are for our understanding of psychology's sub-disciplines; and (c) what new questions we could raise and what kind of research we could conduct that would help place psychology at the heart of an emerging field of possibility studies. My discussion will necessarily be selective, both due to space constraints and the fact that it is meant to be an invitation for further reflection rather than a systematic review of the existing literature. More than this, my hope is to offer a prospective look at old psychological questions, one that integrates agency, indeterminacy, multiplicity, and the future into our concerns, research, and practice.

The Possible in General Psychology and the History of Psychology

If, as noted above, at present possibility research in psychology is still fragmentary and rather scarce, the history of the discipline paints a different picture. Most of the twentieth century currents within psychology were in fact concerned with human possibility, one way or another. Pragmatists, for example, argued for the bi-directional agency between person and his or her context, both social and material (Mead 1934; Dewey 1934). In psychoanalysis, in contrast, the focus was often on closed opportunities due to early life experiences but also on how a better engagement with the contents of our unconscious can expand self-related possibilities (Freud 1922;

Cooper 2013). Behaviorism, for as reductive as it has been in portraying human action, had its followers harbor the belief that everything can be possible for the person given the right kind of environment (Watson 1930). The cognitive revolution opened up the “black box” of the mind in order to examine the ways in which individuals become active in constructing knowledge and, often, how they change their own mental schemas to achieve new outcomes (Neisser 1967). More recently, the narrative turn (Bruner 1991) made us aware of the power of stories and storytelling to transform our reality, including our view of self, others, and society.

General psychology, as the branch that carries the legacy of all these historical orientations, and many more, offers an interesting picture of the mental processes primarily assumed to help us find and explore new possibilities in life. These are, first and foremost, complex cognitive functions including reasoning, the imagination, memory (e.g., constructive memory, Schacter and Addis 2007) as well as motivation (e.g., self-actualizing motives; Maslow 1943). However, such a view masks the important contribution other, more basic psychological processes, such as emotional responses, make to our engagement with possibility. Surprise, for instance, helps us become aware of a new stimulus in our environment and curiosity can prompt us to explore it further and, in the process, discover new meanings and affordances (Berlyne 1978). Perception itself is infused by the possible inasmuch as it does not build a replica of what exists in the world, but it is always driven by present concerns and already oriented toward the future (Gibson 1979).

General psychology and scholars of the history of the discipline would thus benefit from raising more questions about the ontological roots of human agency, the epistemological orientations that make us sensitive to what expands and restricts our sense of possibility and, last but not least, the conceptual tools needed to capture the former and the methodological tools needed to investigate the latter. What do different schools in psychology tell us about human possibility? How do the mental and behavioral processes we commonly study contribute to our engagement

with the possible and impossible in our daily existence? How could we study both in a balanced manner, one that is analytical enough to make key distinctions and yet holistically able to build a bigger picture?

The Possible in Developmental and Life-Course Psychology

Developmental psychology focuses on the emergence of and changes in our psychological functions and behavior across the lifespan. As such, it studies how our capabilities and related set of possibilities develop in relation to the enablers and constraints of a social, cultural, and material environment. It is tempting to see this trajectory as linear and progressing from “more” to “less” and yet, such depictions are often too simple and overly deterministic (an accusation often aimed at key theorists in the field, e.g., Jean Piaget; Piaget 1928). We do not just pass in life from a narrower to a wider range of possibilities but our engagement with the possible depends on a series of factors, including sex, age, family conditions, social and economic status, cultural background, etc. Even when considering age alone, there are ups and downs in how open and ready we might be to explore new ways of thinking, acting, and being. For example, our self-esteem about what we can do does not progress in a linear manner, but tends to slump during adolescence (Robins and Trzesniewski 2005). Equally, creativity – or, rather, divergent thinking – is supposed to peak during preschool years, then decrease in the first and fourth grades, and finally gradually recover, depending on personal circumstances (Torrance 1968).

This complexity is well captured by life-course approaches to human development that tend to consider the co-development of person and context. In this perspective, the study of human possibility cannot be restricted to an investigation of the individual alone, but necessarily has to consider the role of the environment (from small group to community and society) in shaping what is possible and impossible for the person to think, want, or do. This view of interdependence

is extended to how life-course theorists understand all development and makes them more inclined to follow it up to old age (see the entry on the topic in this encyclopedia). Indeed, if developmental psychology tends to have a bias toward younger ages as a privileged site for growth, a life-course perspective is interested by the interplay between possibilities and impossibilities across the entire lifespan.

A key question for developmentalists to raise is how growing up, living, and becoming old in different cultural contexts around the world impacts people’s sense of personal agency and the domains of their life and society in which they could (or are expected to) express this agency. This would not only help us identify those areas in which development is driven forward by an expanded horizon of opportunities, but also examine what happens when this horizon is actively restricted for personal or political reasons. Second, studies of the cultural life-course could benefit from theorizing the possible as a central human concern and fundamental type of experience across ages and contexts. This would expand existing research into the role of imagination across the life (Hviid and Villadsen 2017) and shed new light on particular contexts such as migration, education, work, etc.

The Possible in Personality, Cognitive, and Neuropsychology

Individual differences psychology studies the psychological profiles of individuals according to various indicators (mostly related to personality and cognition, but not only). Neuropsychology, as the subfield situated at the interface between psychological science and neuroscience, tries to locate these individual differences within neural mechanisms and biological processes. While it might seem that possibility is too complex to ever be “mapped” onto the brain’s activity, it is undeniable that neurological mechanisms contribute to the phenomenon through their relation to psychological functions like sensation, perception, affect, and decision making (although the exact relation between these processes and their

biological basis has been and remains a matter of debate; see Miller and Keller 2000). Relating human possibility to neuroscience also reminds us of the embodied nature of exploring options, taking decisions, and envisioning alternatives in everyday life.

At the level of personality and cognition, there are a series of processes widely assumed to contribute to our engagement with the possible. For personality, these include traits like openness to experience and tolerance of ambiguity. Such dimensions have been consistently shown to correlate with creative expression (Runco 2007) by making the individual sensitive to novel stimuli in his or her environment and able to withstand longer periods of tension, confusion, or not knowing. In terms of cognition, creativity is considered to relate closely with divergent thinking, or our ability to think of many plausible solutions for an existing problem, and lateral thinking, the capacity to pursue even weak connections between ideas that can lead to creative insight (Gilhooly et al. 2015). When it comes to creative imagery, the possibility of building images in the mind and combining them with each other in new and unexpected ways becomes essential (Finke 2014). And if we are to expand the range of interest from cognition to affect and motivation, we can discuss how intrinsic motivation participates, for example, in achieving a state of flow highly conducive for invention and discovery (Csikszentmihalyi 1997).

In summary, the psychology of individual differences can make significant contributions to our understanding of person-level characteristics and processes that participate in our awareness and exploration of the possible. But, as noted from before, it is equally important to understand the expression of these characteristics as a function of the overall situation and life trajectory of the person. Just like neuroscience can provide knowledge as to how the brain operates when we image, create, or innovate, we should not lose sight of the fact that the brain belongs to a body and to a person that is embedded within a specific context, at a certain moment in time. As such, useful questions from this perspective would consider how individual attributes shape and are

shaped by living in a society together with other people and within a history that is, at once, personal and collective.

The Possible in Social and Sociocultural Psychology

The latter are, in fact, the kind of questions typically raised by social and sociocultural psychologists who study the human mind and behavior in their social context. There are, of course, some key differences between the two branches. Social psychology is concerned with interpersonal, group, and inter-group processes and the way they come to shape individual and collective actions. Sociocultural psychology emphasizes the fact that these are not only “external” influences, but the social environment and our interactions with other people are constitutive for the human self (see Mead 1934). Both approaches have thus a lot to tell us about the experience of possibility (and impossibility) for individuals, groups, and communities. However, because of the difference noted above, scholars in these subfields tend to reach different conclusions about human agency in society.

Going through a social psychology textbook, anyone would be forgiven if they believed that other people often reduce our range of possibility or, even worse, lead us to committing unthinkable acts. From conformity and obedience (Milgram 1974) to crowd behavior (Le Bon 1896) and the bystander effect (Latane and Darley 1968), social psychology is full of cautionary tales about social interaction and its consequences. Society is often, even if implicitly, described as an oppressive force that molds and sometimes squashes individual freedom and sense of the possible. The notion of de-individuation, a process presumed to take place in certain social contexts in which the person becomes “less” himself or herself and takes on the attitude and behavior of others, is a classic example in this regard (Diener 1979). On the other hand, socioculturalists would argue that even if some situations push us, more or less, into doing things we would not normally do, it is also the case that there would be no human agency

without social interaction and exchanges of position (Martin and Gillespie 2010) to begin with. Indeed, it is in and through the self–other relation that we experience the world as another person would, develop new perspectives on it, and get to understand our own perspective as one among many (Glăveanu 2020), all of these important, possibility-enabling processes.

Interesting questions to raise within this approach have to do with the kind and type of human relations that constrict or foster our agency (or do both). Do face to face, close relationships matter more in this regard than distant relations established, for example, with people we admire but might have never met or with generic audiences like the general public? Following from this, how do we establish those human interactions that do cultivate the possible in our existence and how do we maintain them? Most of all, how does society participate to individual and collective agency through its norms, values, technologies, and institutions? Instead of adopting reductionist accounts of the collective as mindless or dangerous, possibility studies scholars in social psychology would do well to explore sociability as the origin of creativity and one of its key drivers (Simmel 1949).

The Possible in Work and Organizational Psychology

The interest in creating possibility-enhancing conditions for individuals to perform their tasks well is at the heart of work and organizational psychology. These sub-disciplines, although distinct, are both concerned with how individuals and groups function at the workplace, within an institutional context. If, traditionally, the workplace has been a context in which people exercised their habits and applied their existing knowledge, more and more we are witnessing a radical transformation of mentalities and requires skillsets. Instead of routine and predictability, jobs are demanding the creative handling of uncertainties and quick processes of adaptation to changing conditions (there is little surprise, then, that creativity is listed among other key twenty-first century skills;

Trilling and Fadel 2009). In other words, an openness to and anticipation of what is possible becomes a requirement for most employees instead of a luxury reserved for the few, primarily in managerial positions.

The interest in possibility is reflected by work done on leadership and, in particular, the intersection between leadership styles and creativity (Hughes et al. 2018). Also by the long-standing concern for how groups create and what might be the obstacles but also facilitators of team innovation (Reiter-Palmon 2017). A particular emphasis in this regard, reflecting the high levels of diversity at work, is placed on multidisciplinary teams and the ways in which they use differences as a resource (Ness and Riese 2015). Innovation has been and continues to be a key concern for work and organizational psychologists (Anderson et al. 2014), especially the factors that promote risk taking and help employees both appreciate and look for novelties at the workplace. Organizational learning and change are established subfields of research (Todnem By 2005) that are expanding today in new directions as a consequence of distributed forms of possibility.

And it is precisely this distribution and “democratization” of what it means to find and exploit new and exciting potentials that should be of interest for work and organizational researchers moving forward. The fact that, for instance, it is not only leaders today that are expected to initiate and manage change processes, but each and every employee (the theme of followership is already discussed; see Uhl-Bien et al. 2014). In addition, we need to distinguish between possibilities and impossibilities situated at the individual, group, and organizational levels. While it is easy to assume that the latter frame the former, we need to acknowledge the fact that change takes place at many levels within an organization and that, sometimes, individual actions can open up new horizons of possibility for everyone else. Just as top-down transformations can still be participative in how they are implemented. Of course, the question is how these change processes are received and how organizational climate and culture cultivate (or not) openness to novelties,

respect for difference, and an authentic curiosity about the future.

The Possible in Clinical and Therapeutic Psychology

I have noted before that living within worlds of possibility and developing possible selves is the ontological condition of human beings. Clinical psychology, and especially the study of psychopathology, helps us problematize the issue of what is “normal” and focus on conditions that, one way or another, restrict certain possibilities for the individual (while potentially opening up others, previously unnoticed or underused). It would be simplistic, though, to associate clinical psychology with the sign of reduced possibility. On the contrary, we can use its study as an opportunity to expand our own understanding of what is normal, “natural”, or universally human. As the subfield of ethno-psychiatry shows us (Gaines 1992), we need to be cautious when assuming that some specific possibilities need to be noticed or actualized in order to have a fully human existence. These assumptions usually betray Western-centric assumptions about how life should be lived and, especially, what counts as worth doing in life. On the other hand, for some time the study of disabilities has been moving toward an understanding of special conditions as potential resources when seen from a new perspective (e.g., the idea of being differently abled). And also toward helping those being diagnosed and their care-givers to actively explore such possibilities. Last but not least, the diagnostic itself can be a useful for making meaning about one’s condition but it could also be used as a label for what becomes possible and impossible for the person, especially when employed by other people (for discussions about diagnostic culture and psychiatry see Rose 2018).

Therapeutic and counseling psychology, conversely, are much more directly oriented toward appreciating the person’s potential and helping him or her achieve it, above and beyond the constraints of a diagnostic. Therapists work with their clients to help them understand the root of

experienced impossibilities and think of ways, if not to overcome them, then at least to turn them into opportunities for personal transformation. While there are many therapeutic approaches – ranging from psychoanalysis to cognitive-behavioral therapies and humanistic or existential orientations – this possibility-extending ethos is central for most. Some therapies, especially drawing on humanistic psychology and a client-centered philosophy (see Rogers 1951), are explicitly aimed at creating the context for an in-depth exploration of the possible let by the client himself or herself. Ultimately, the kind of questions clinicians and therapists can raise more often concern precisely the consequences of opening up such spaces for the person and for the counseling relationship. Confronting and understanding one’s impossibilities is a fundamental part of the process and these branches of psychology can shed new light on the best ways in which patients or clients can be helped through this difficult process that is, ultimately, one of self-transformation as much as it is one of self-discovery (Hermans and Hermans-Jansen 1995).

The Possible in Learning and Educational Psychology

The related branches of the psychology of learning and educational psychology are explicitly concerned with cultivating human possibility, specifically through learning and education. Learning is, just like creativity, an act of engaging with the possible by expanding the ways in which the person understands and acts on the world. And yet, oftentimes, the process of learning is seen as primarily one of acquisition and not necessarily transformation of knowledge. Jean Piaget usefully considered, in this regard, that the development of intelligence involves both assimilation and accommodation (Piaget 1928) and that, in other words, the individual does not just acquire a new mental schema but changes, through accommodation, his or her existing schemas in order to anchor the new into the old. Of course, there are other possibilities opened up by learning and intelligent behavior; for instance, the new stimulus can be

explored and transformed before it changes existing knowledge. Also, we can question whether “pure” assimilation exists in the sense of adopting the new without any additions or emergent processes. To learn, thus, is not reduced to reproducing, within one’s mind, what already exists in the world or the minds of others; it is necessarily a dynamic, adaptive, and transformative process in which learners consider not only what is the case, but also what could be and how things become.

This possibility-based understanding of learning has been central to an educational psychology focused on teacher–student interactions within both formal and informal contexts. Just like general psychology, this branch uses different approaches – from behaviorist to cognitivist and experiential – in order to derive principles for education. Some of these, as noted before, can be more restrictive of the possible, especially those operating with the basic stimulus–response schema of conditioning. This is how, for example, educators are often accused (still) of harming rather than enhancing their students’ creativity and imagination (Robinson and Aronica 2015). It is the emphasis on rote memory and the reproduction of knowledge without any significant transformation that underpins this critique. And yet, if we look toward operant forms of conditioning, we soon notice that learners do have some agency in determining their own “stimulations.” These insights have been carried over by Bandura (2001) into his social cognitive theory. This approach is based on the bi-directional relation between person and environment and brings to the fore those mental constructions and anticipations that drive our behavior and, ultimately, our success in education and beyond. Self-efficacy, for instance, is a concept based on the incorporation of possibility within one’s self understanding (see the dedicated entry in this encyclopedia). These conceptions are not new. Lev Vygotsky, from the first half of the twentieth century, promoted a sociocultural view of learning and education based on the zone of proximal development (see, as well, the dedicated entry in this encyclopedia) or the notion that learning drives development by creating a space of possibility for our

actions, especially when interacting with others (or more capable peers, in Vygotsky’s terms).

New questions for learning and educational psychologists when it comes to human possibility have to do with the role of power and inequality in society and how these impact what learners (and teachers alike) can think and do. Paolo Freire raised this important issue decades ago (Freire 1973) and his efforts to work with marginalized and oppressed communities toward their emancipation resonate today with the struggle against oppression and discrimination of many people around the world. Pedagogies of the possible (see Glăveanu 2020) can only be based on a critical understanding and engagement with the world in order to reimagine it through the process of learning and education.

Conclusion

In conclusion, psychology as a multifaceted discipline has a lot to offer any scholar interested in possibility studies. By focusing on the mental states, actions, and experience of people in a variety of contexts, as well as across time, psychology is also very close to other disciplines and their own approaches to the possible. For example, general psychology is connected to philosophy, as the two disciplines have been historically. Cognitive psychology builds on the achievements of cognitive science, neuroscience, and artificial intelligence. Social and sociocultural psychology are close to sociology and anthropology, organizational psychology to management, and educational psychology to pedagogy and the sciences of education. In each case, psychologists can inform and also learn from the approaches and findings of connected disciplines. This is how, for example, the possibility-related vocabulary used by psychologists (including divergent thinking, self-efficacy, counterfactual thinking, etc.), can be enriched by philosophical approaches to the imagination, managerial views of innovation, or sociological studies of agency and structure.

If psychology is to fully contribute to these dialogues, however, it needs to strengthen its commitment to a dynamic and relational ontology

(Slife 2004) and an epistemology that considers the world as mobile, multiple, and open to the possible and to the future. We also need to develop methodological tools that do not immediately stabilize or reify reality but allow us to study psychological phenomena as they emerge and develop in (inter)action. This kind of work is underway in many subdisciplines of psychology and we can hope that the notion of human possibility will continue to inspire theoretical development, empirical research and, most of all, the practice of psychologists in the twenty-first century.

Possible in Scriptwriting

Samira Bourgeois-Bougrine
Université de Paris, Paris, France

Abstract

Scriptwriting is a creative and collaborative practice of utmost importance for the film industry. It opens up various possibilities for

the story to be told. The process of scriptwriting resembles the act of wandering through a “maze of possible” including true paths (good ideas) and blind alleys (unsuccessful ideas/blocks). The present entry focuses on how the scriptwriter navigates this “maze of possible” from the preliminary stage of a “formless” situation where there is no structure to the “exit” of the maze represented by “final” version of the script. More specifically the following questions will be addressed: What are the origins of cinematic ideas? How is an idea nurtured and developed into a script? Answers to these questions will be grounded in the neuropsychology of creativity. The conclusion will address possible research questions specific to scriptwriting such as “how might creativity be improved to reduce writer’s blocks? How screenwriting might operate in cinematic virtual reality? Could creative scripts be considered worthy of publication?

Keywords

Scriptwriting · Creativity · Psychology · Neuroscience · Attention

Introduction

Alfred Hitchcock said, when asked what is the most important part of filmmaking, “the script, the script, the script” (Truffaut 1968). A script is a written work for a film, documentary, TV show, or video game. Of these, the present entry will mainly address motion picture screenplays, which are considered as the blueprint, the heart, and the backbone of a movie. A written script includes mostly characters’ names, their movements, actions and dialogues, descriptions of settings, information about where the scene is set (inside or outside), its specific location, the time of day, etc. It is also expected to conform to a proper formatting that specifies how these elements are presented on the page, the font size and line spacing, etc.

Beyond these specific standardizations, writing a script opens up possibilities and provides alternative ideas. It involves imagination, creative

writing skills, as well as decision-making and problem-solving skills. Previous research (Bourgeois-Bougrine et al. 2014) has revealed a series of distinct but interrelated stages in screenplay writing starting, in general, from a long and enjoyable phase of impregnation, followed in some, but not all cases, by a formal phase of structuring (writing up an outline and or treatment) and, finally, intensive periods of writing and rewriting the script. These three stages, and in particular the multiple and concrete decisions to be taken within the writing stage, resemble the act of wandering through a “maze of possible” sometimes laboriously and sometimes effortlessly with a feeling of being “carried over,” described as being in a flow state (Csikszentmihalyi 1996). Scriptwriters prepare for this “journey,” create “maps,” and then enter the maze navigating through various true paths (good ideas) and blind alleys (unsuccessful ideas/blocks/obstacles/constraints/problems). The writer progresses down the maze by trial and error, retracing his or her steps, progressing meticulously by seeking advice, consulting and updating the “map,” responding to internal and external stimuli or cues, etc. Frustration increases after experiencing many obstacles, entering several blind alleys, going back over and over and getting lost. However, the writer may traverse the maze quickly in an intuitive or automatic way if the path to follow is clearly indicated (e.g., book adaptation) or if he or she had already experienced a similar maze (e.g., TV series format) and had learned how to navigate by developing a sort of cognitive map of where many of the blind alleys are (Bourgeois-Bougrine et al. 2014).

The present entry uses central ideas from a number of psychological and neuropsychological theories to highlight how the scriptwriter navigates this “maze of possible” from the preliminary stage of a “formless” situation where there is no structure to the “exit” of the maze represented by “final” version of the script. Moreover, using a same set of interviews that informed a previous work (Bourgeois-Bougrine et al. 2014), this entry mines those same discussions for answers to some of the most fascinating questions: where do initial cinematic ideas or concepts come from and how

do new ideas emerge throughout the writing process? The conclusion will rise possible research questions specific to scriptwriting such as how might creativity be improved to reduce writer’s blocks? How screenwriting might operate in cinematic virtual reality? Could creative scripts be considered worthy of publication?

Where Do Original Cinematic Ideas Come From?

The psychology of creativity considers creative action, such as scriptwriting, within the creative problem-solving framework (Lubart et al. 2003, Bourgeois-Bougrine et al. 2014). A screenwriter who seeks to express his or her feelings in an original way is considered to be involved in solving a problem. Creative problem solving involves the ability to make nonobvious connections and the ability to generate new solutions previously unknown (Lubart et al. 2003). A problem¹ can be defined as: “A situation for which the organization has a purpose but does not have a known means to achieve it.” Einstein (in Getzels 1979) made a distinction between the detective and the scientist both of whom seek solutions to problems: “For the detective the crime is given, the problem posed: Who killed Cock Robin? The scientist must at least in part, commit his own crime.” Under this understanding, creative action can either start with a demand (problem posed) or originate through the creator. Depending on whether the “problem” already exists (a book to adapt, an existing script) and who propounds it (self or others), the creative process would be more or less demanding. So, in a manner similar to a detective, a scriptwriter could be hired by a director, a producer, or a sponsor to adapt a book for the screen, modify an existing script, etc. Alternatively, like a scientist, the scriptwriter would have to come up with the initial idea of the film. According to some scriptwriters, this initial idea of a film is something that “*haunts them or talks to them*”; they have a “compelling” need to

¹ http://edutechwiki.unige.ch/fr/R solution_of_problem

tell a story and it results from a coincidence or happens by chance, (e.g., it could be triggered by a photo, by something seen or heard) or it is linked to something autobiographical or which resonates with the writer's own experiences, etc.

Scriptwriting, as in any artwork, does not arise from conceptual void but from an extensive knowledge base (Bourgeois-Bougrine et al. 2014; Mace and Ward 2002). This knowledge is constantly developed as a result of the writer's previous experience, explicit and implicit understanding of filmmaking techniques and skills, personnel interests, historical and contemporary cinematic and art knowledge, etc. Professional scriptwriters are indeed always "receptive," like "sponges," tend to take note of diverse information and record interesting ideas for possible future use and are open to internal and external stimuli. Openness, which is described as an appreciation for aesthetics, preference for novelty and intellectual curiosity, is one of the personality traits that is strongly associated with creativity through the expansion of the knowledge base and serendipitous encounters (Costa and McCrae 1992; Batey and Furnham 2006; Kaufman 2013). Indeed, it has been suggested that high open-minded individuals have defective filters for irrelevant stimuli, which then leads to more thoughts entering consciousness, which, combined in interesting ways, form creative ideas (Batey and Furnham 2006). Recently, Agnoli et al. (2015) established that attentive processing is a central psychological mechanism to explain the relationship between openness and creativity. Using eye-tracking methodology, they showed a moderating effect of irrelevance processing, with creativity reaching higher levels in individuals characterized by a high level of openness and who gave attention to irrelevant information. Indeed, creative people have been characterized as tending to have more defocused or broad attention span leading them to attend to a large range of stimuli at any one time (Kasof 1997). Individuals with chronically narrow attention span tend to filter or screen out irrelevant stimuli from awareness and, therefore, are unaffected by their surroundings. According to Dorfman et al. (2008, p. 1383),

"defocused attention may be caused by reduced cognitive inhibition, where inhibition is understood as a mechanism that can restrict the flow of information into the focus of attention. The consequence of reduced cognitive inhibition is that more information is allowed into the focus of attention for processing." Martindale (2002) suggested that rather than having a stable disposition toward defocused attention, creative individuals adjust the scope of their attention according to the task demands: when solving problems that call for creativity, they tend to have defocused attention, and in other situations, they are better than uncreative people at narrowing the focus of their attention.

The question related to the emergence of the initial cinematic idea echoes with "problem finding," which correspond to the stage of "formless" situation where there is no structure, no task, no problem to solve (Getzels 1979). Creative action is not determined in advance and difficulty for writers resides in being able to recognize the potential of an idea as suggested by a scriptwriter (Bourgeois-Bougrine et al. 2014):

For an original script, I start from a situation, which seems interesting or funny. Then I try to see where it will lead me. In most cases, I don't know where I am going. Things build up gradually, and the meaning of all this emerges very late and sometimes not at all.

The myriad of ideas to explore within the maze of possible requires the ability to sense the artistic potential of an idea and the way to unleash it. To quote Getzels (1979, p. 167), ideas do not present themselves as "problems capable of resolution or even sensible contemplation. They must be posed and formulated in fruitful and often radical ways if they are to be moved toward solution. The way the problem is posed is the way the dilemma will be resolved." As Einstein (in Getzels 1979) put it: "The formulation of a problem is often more essential than its solution, which may be merely a matter of mathematical or experimental skill. To raise new questions, new possibilities, to regard old questions from a new angle, requires creative imagination and marks real advance in science." As reported below, screenwriters, in general, have

difficulty getting started when considering writing a script based on an idea; they “*turn around the film idea*,” reading, and collecting information, etc., before initiating the actual writing:

I am starting a new project and currently I am turning around. It's a kind of ritual: I am turning around the topic like wolf around its prey

I find it hard to tackle the job head on. I first circle, I turn around it (*je tourne autour*). when I find a good idea, or a scene that I like, I turn around it. Generally, I do a lot of things that are indirectly related to the work, I read a lot, I copy many texts that interest me, I see a lot of movies, I listen to a lot of music... I do many things around the work which I think will be the foundation of the work itself.

When a scriptwriter is commissioned to write a script based on a director or a producer's concept or original idea, the creative process starts by meetings the sponsor in order to understand the demand and extract the gist of the original idea of the film. During the initial meetings or “sessions,” the writer considers the script project in terms of “why” rather than “how” and, just as in “talking therapy,” he or she tries to understand the director's motivation behind the project of the film through daily discussions without censorship. This stage is equivalent to the definition or reformulation of the problem to be solved. The openness, trust, and pleasure in sharing ideas and desires that characterize these meetings might lead to a positive mood and a feeling of freedom to explore unconventional ideas about the story to be told and to develop the personality and the biography of the main characters. In this phase, there is a lot of “why...”, “I would like...”, “what if...”, and openness to whatever comes. This collaboration engenders a myriad of possibilities. Illustrating the collaborative nature of creative endeavor, one of our participants noted that:

Speaking more generally, an artwork is largely a ‘delivery’. In the film industry, it is a ‘delivery’ involving lot of midwives as well as surgeons and hospital staff. Producer, technicians, writer, etc., should help a director to give birth to an idea dear to his heart. (S18).

Moreover, research suggested that events happening in the distant future (like, for example, a

film project which takes up to 4 years to be completed) are represented in a more abstract, structured, high-level manner. According to construal level theory (CLT), a framework that links processing styles and psychological distance (Lieberman et al. 2007), processing information in a global, abstract, and explorative way helps in finding creative solutions and ideas (Förster and Dannenberg 2010). At the same time, the feeling of being free from constraints (Steidle and Werth 2013) and in a positive mood (Labro and Patrick 2009) elicits abstract thinking and promote creative idea generation. Moreover, Lieberman et al. (2007) showed that individuals “would engage in an activity at a later point in time when it was described in abstract (rather than concrete) terms, when they had first considered why (rather than how).” As suggested by McCrea et al. (2008), mental association between level of abstractness and temporal distance is a bidirectional relationship: events that are distant in time tend to be represented more abstractly than events that are close in time and the level of representation of an event have effects on the time when the activity is performed. In other words, procrastination increases when thinking about the task in abstract terms rather than in concrete ones.

Indeed, scriptwriters put lots of emphasis on allowing the mind to wander freely: reflecting, thinking, daydreaming, reading, and collecting information, etc., before starting the actual writing. The findings of neuroimaging studies of the brain indicate that when individuals are given the instruction to “relax and simply think about whatever comes into their mind,” brain areas, which are referred to as the default mode network (DMN), are engaged. The DMN is activated by diverse forms of tasks that require spontaneous activation of autobiographical and semantic memory, perspective-taking, envisioning the future, and moral decision-making (Buckner et al. 2008). As pointed out by Binder et al. (1999), such activations are adaptive: “by storing, retrieving, and manipulating internal information, we organize what could not be organized during stimulus presentation, solve problems that require computation over long periods of time, and create

effective plans governing behaviour in the future.”

These conscious and unconscious processes result in the extraction of the gist of the original idea of the film and boost the associative search for creative solutions using the collected information, introspection, past experiences, and thoughts. The biography of main characters is refined and a schematic representation or “map” of the story emerges turning an abstract goal into the more concrete specific steps necessary to achieve the goal. However, some writers who, in general, disliked the development of formal map or script architecture seem to wander aimlessly in the maze of the possible:

“I’m going in all directions, like a hunter who wanders in a forest.” / “I start writing the scene, I know roughly where I want to go, even though I do not really know how to get there, etc.”

How a Creative Idea Develops into a Script?

The process of idea development refers to the period of writing and rewriting the script. The writing process could be considered as a cycle, alternating between generating creative ideas and evaluating their potential through “a continual testing of and discarding of ideas as to their suitability for the story” (Nelmes 2007, p. 111). Quite often while developing dialogues and scenes, what has been planned can be abandoned; new ideas are generated, tested, and implemented which will have an impact on what has been already written, a classic “domino effect.” The choice between new alternatives or ideas leads to the rewriting or suppression of previous dialogues and scenes. These processes occur in a cyclical manner until the task is completed.

Indeed, literary creativity, which involves the ability to flexibly combine concepts stored in memory to form novel and useful associations, requires the co-activation of large brain networks: the default mode network (DMN) which is known to support the divergent and open creative process and the control executive network

(CEN). The CEN is a goal-directed processing which exerts a control on our thoughts and actions, controls attentional shift from the external word to internal thoughts, facilitates flexible switching between semantic categories during memory retrieval and in mitigating sources of interference by suppressing salient conceptual knowledge. Recent study showed that during creative writing, expert writers relative to non-experts demonstrate enhanced brain activity in the CEN during creative writing (Erhard et al. 2014). Moreover, writing experience index (number of weekly writing hours and number of years of practice) is positively correlated with the gray matter volume in brain regions linked to executive functions, such as working memory and planning processes in complex cognitive tasks (Neumann et al. 2018).

Experience seems, indeed, to facilitate the automatization of some processes as complex as building a story or adopting a 90 min:

I have the impression of having acquired a certain competency regarding these fundamental questions: how to construct a story, depart from one already written, how to write dialogues that don’t sound too awkward, how to enter a scene and end it without getting lost.

Writing is a matter of ‘breath’. A story of 1 hour 30, it is a bit like an athletic discipline: the more you practice, the more you are comfortable. But I’m useless when I have to write a short film! What’s crazy is that, almost by magic, by experimentation as well, the rhythm of 90 minutes becomes natural. I have great difficulty with other rhythms.

The discourse of scriptwriters suggests that the creative writing process is driven not by the plot or the structure, but rather by the characters, the emotions they elicit, and consequences of their “actions” on past, present, and future events. In addition, they reported that as one “*gets into the skin of the main character*,” “*understands the character*,” and “*makes him talk*,” they experience often enjoyable moments where intuition, unconscious, and automatic process take over the generation and selection of creative ideas. The empathy with the characters leads to the feeling that they came to life and make the choices instead of the writer,

“hijacking or guiding the story line in unexpected ways” as reported by Australian fiction writers (Paton 2012). This sense of being “carried over” designates a temporary loss of self-consciousness characteristic for the flow state (Csikszentmihalyi 1996). Could the co-activation of default and executive networks, which reflect focused internal attention on thought content, explain the deep concentration that characterizes the flow state? Future research in neuropsychology of creativity could explore this hypothesis in order to develop trainings or inductions methods to facilitate the occurrence of the enjoyable and creative moment of flow state.

However, the creative process, which is associated with positive emotions such as pleasure and jubilation when a bright idea is found, becomes painful when writers experience blocks. Frustration increases when experiencing lot of obstacles, entering several blind alleys, going back over and over and getting lost within the maze of the possible. Sometimes “*the created characters or the situations they are in lead to impasses or deadlocks.*” Solving these problems, obstacles, impasses, or deadlocks involves different strategies that could be used alternatively: a confrontational strategy; seeking support and opinions; and rational analysis (Bourgeois-Bougrine et al. 2014). Writers spend hours “fighting” with the problem, which leads often to fixation or mental block. It becomes impossible to go back, and impossible to consider other solutions:

There are moments when you feel it just turns around and you are not getting anywhere

Often it is the case that we struggle for a very long time only to settle the problem with one line . . . But if I struggle it is because I am not wise enough to notice that the situation is not good. I try to solve the problem artificially, but the characters cannot exist in that situation.

Interestingly, solutions might also emerge when scriptwriters step back from the manuscript or do something that is not related to it. Indeed, the solution could occur during unrelated tasks (e.g., emptying the washing machine, bathing a child,

taking public transport, or working alternatively on another film project in a less demanding phase, etc.):

I struggle and when I am saturated with a project, being able to switch to another project frees my mind and allows me to find answers to the first. . .

Like in painting, you need to let it dry. You write a version and then let it rest . . . then retake it. Because it's very hard to see it when you have your nose in it. It is exactly like in painting: if you have blue and want it to be red and it is not dry it will become brown.

Studies on the deliberation-without-attention effect show that a period of unconscious thoughts or incubation while making complex decisions can actually lead to better decisions than a period of thorough conscious deliberation (Dijksterhuis et al. 2006). There are at least two hypotheses that could explain the assumed superiority of unconscious thought: it might be the product of an active unconscious processing capacity of information or the result of a differential rates of forgetting of attributes of the various options. Previously acquired knowledge and prior experiences can indeed limit creative idea generation, leading to mental fixation. A distraction with an easy task, a period of rest or incubation would, therefore, help to overcome the constraining influence of recently activated knowledge.

Finally, writing a script for a movie is a deeply collaborative creative process. It involves iterative phases of private writing of drafts and collaborative interactions to analyze these texts and provide feedback that leads to a new draft. The process of rewriting several versions of a script seems to be universal among screenplay writers, engaging often the director and the producer of the film as well as actors and other members of the film crew. Ultimately, a final version of a script is virtually impossible as scripts are often modified before and during the shooting, as well as during the movie editing stage. This leads to a working context which is simultaneously individual and social and fosters interactions with others that can be, at times, a source of tension and frustration (Condor 2010) when the contribution of the scriptwriter or co-writer is not

recognized enough, leading to uncomfortable and ambivalent feelings.

Conclusion

In contrast to the myth that creative ideas result from a “dreaming” person having a flash of insight, new ideas and solutions are the result of an ongoing knowledge base development, discipline, and daily hard work (Paton 2012; Bourgeois-Bougrine et al. 2014). Professional screenwriters engage in conscious work even when not inspired, focusing their attention on the task, developing ideas, solving problems, and taking decisions or making choices between different alternatives. The neuropsychology of creativity highlights possible underlying mechanisms that promote the emergence, the selection, and the implementation of creative ideas during scriptwriting. Creative production is considered to be a result of both uncontrolled spontaneous associative thinking and controlled goal-directed effortful thinking. The writer could traverse the maze quickly in an intuitive or automatic way if the path to follow is clearly indicated (e.g., book adaptation) or if he or she had already experienced a similar maze (e.g., TV series format) and had learned how to navigate by developing a sort of cognitive map of where many of the blind alleys are.

Among the possible research questions in scriptwriting, one which holds a particular importance for script development is “how might creativity be improved to avoid or reduce mental fixation?” Recent studies have examined the impact of different motor and cognitive trainings or inductions methods on creative performance (Abraham et al. 2019, Oppezzo and Schwartz 2014). The aim of these methods is to induce a change in the usual pattern of information processing to improve creative cognition. However, more research is needed to clarify the mixed and sometimes contradictory findings (Abraham 2018). For example, due to the diversity of the experimental tasks and design, there is no agreement with regard to the role of

inhibition in creative idea generation and fixation. Future studies should explore the issue of attention control in the context of scriptwriting.

Another research question could focus on the status of the script. A screenplay is almost never seen by audiences outside the film industry leading in some cases to a lack of social status, public and media recognition for scriptwriters (Simonton 2011; Bourgeois-Bougrine et al. 2014). Some scholars even wonder whether creative scripts could be considered worthy of publication. Indeed, Baker (2016, p. 1) argued that scriptwriting is a practice that deserves scholarly attention and that academic scriptwriting has a strong critical research. He indicates that “there has been a persistent idea that scripts are not stand-alone works but merely ‘blueprints’ for the films or television programmes based on them. This situation is now changing, with a number of academic journals publishing screenplays as creative research and treating scripts as texts in themselves, irrespective of production.”

Finally, a promising question could be: how screenwriting might operate in the emerging medium of immersive or cinematic virtual reality (CVR)? Contrary to traditional 2D movies where the viewer discovers the story as constructed by the scriptwriter or filmmaker, CVR allow the viewer to decide where to look around the whole 360-degrees. He or she could miss important visual details of the story and become lost or confused. As CVR is 360-degree media, recent studies highlighted the need to explore new ways of thinking and seeing the potential for the development of screen ideas in this medium (Ross and Munt 2018; Rothe et al. 2019). The questions raised by scriptwriting scholars are as follows: how to guide viewer’s attention in an unobtrusive way? What format can be used for delivery of the CVR screenplay? How to address the question of spatialization of the screenplay for omnidirectional movies? What is the impact of immersive movies on people’s thoughts, behaviors, and emotions? In the context of CVR, writers will have to adapt to a dynamic maze of possibilities rather than static one.

Possible in Sociology

Steven Lybrand¹ and Richard Randell²

²Webster University Geneva, Geneva, Switzerland

Abstract

Sociology – as both science and mode of societal self-reflection – was made possible by the conjunction of mid-nineteenth century European philosophical thought with the historical crises erupting within the emerging industrial societies in the West. Sociology, once established, evolved to make possible a proliferation of perspectives for studying a newly constituted ontological space identified by Auguste Comte. What, exactly, that ontological space denotes and how it is to be studied is at the center of debates within contemporary sociology. For Comte, sociology promised nothing less than a scientific blueprint for the reconstruction of society; a possible world that would be free of conflict, strife, and, especially, what he considered to be the disease of the West: individualism and its quixotic attachment to freedom of thought. To others, such a deterministic, authoritarian perspective was a precursor of the totalitarian societies of the twentieth century. Understanding this genealogy and imagining what possible worlds might await us is the unfinished business of that discipline that goes by the name “sociology.”

What Is Sociology?

The term sociology denotes not only an established academic discipline but also a broader intellectual perspective for understanding behavior, institutions, and cultural life. Sociology occupies a liminal disciplinary and intellectual space. On the one hand, it has carved out for itself a space as a legitimate social science. On the other hand, it is held in suspicion by those who see sociologists not as rigorous scientists but as all-purpose commentators on social and political life. Allegations that sociology is merely common sense or gussied up ideology masquerading as a science have accompanied the discipline since its inception (cf. Marx's [1866] critiques of Comte's “shitty positivism” and his curt dismissal of the Utopian Socialists). Where one stands on the reputational divide in respect to sociology will determine what one thinks sociology might or might not make possible (or declare impossible).

One straightforward and seemingly uncontroversial way of fixing what academic sociology *is* involves looking at what sociologists *do* when doing their job as sociologists. In addition to producing texts, sociologists teach and create and maintain disciplinary institutions, such as professional associations and academic departments in universities and colleges. They also work as intellectual workers in government and industry. A complete resume here would require the recounting of a comprehensive history of the discipline, in the diverse locations it has appeared, as well as an account of the current

state of the discipline, the objects of study constructed by its subfields, and a summary of the diverse theoretical paradigms employed by sociologists across its subfields of research. The construction and maintenance of all these institutional and cultural spaces may be considered one of the achievements of sociology. It has made *itself* possible.

To summarize the history of the institutionalization of sociology is beyond the scope of this entry. The reader who wishes to appraise herself of the current empirical fields and theoretical paradigms of sociology could do worse than peruse a contemporary introductory textbook. Perusing the lists of subfields of sociology of the International Sociological Association, or the American, British, French, German, and other national sociology associations, will also give the nonsociologist a reasonable overview of the breadth of contemporary sociology. There is a sociology of virtually everything. There are few aspects of human life, from the mundane and micro in scope – the routine activities of everyday life – to the exceptional and macro – social movements, wars, and revolutions – that have not been studied by sociologists. Since its origins in the mid-nineteenth century, sociology has taken as its potential subject matter virtually all of contemporary, and past, human existence. It is not, of course, the only academic discipline with such an ambitious resume. History and anthropology and philosophy have also laid claim to such a wide-ranging intellectual agenda.

What, then, is specific and unique about the texts of sociology? Beyond the fact that they were written by professionally certified sociologists, what makes an empirical study or a theoretical text an instance of sociology? Do the credentials and institutional location of its author suffice for designating it as “sociology,” or is it enough that someone write about intellectual problems that fall within some assumed territorial boundaries that the discipline has come to acquire over time? Put another way, does sociology possess some kind of essence? This question invites a less straightforward and uncontroversial way of fixing what academic sociology might be. Across

the myriad collection of sociological concepts, theories, paradigms, and empirical studies, is there something that unites all these diverse concerns?

Medicine, Michel Foucault (1994) argued, may be considered the first of the human sciences, in having constructed “man” as an object of scientific study. Whereas previously it was only the external world – the world of “nature” – that had been constructed as an object of scientific study, modern medicine marked the transition to a new episteme wherein the human being was configured as both subject and object of the newly developed scientific gaze. Sociology sits within this epistemic reconfiguration. Its focus has been not the individual in isolation but the properties of human collectivities. Although reflection on phenomena related to human association predates recorded history, the burst of social thought following the French Revolution was seminal in the creation of this new discipline (Manuel 1962, Salomon 1962). Auguste Comte (1798–1857) is recognized as the founder of what was to become the discipline of sociology. Comte’s construction of sociology as a “positive science” was primarily a distillation of streams of thought bookended by the Enlightenment and Romantic periods within Western social thought.

A science of modernity, sociology developed in Europe following the collapse of feudalism and the *régimes anciens*, and the French Revolution; the Enlightenment and subsequent death of God, as Friedrich Nietzsche diagnosed our predicament; and the rise of capitalism, industrialization, and later of Soviet communism. A product of modernity, sociology has a triple genealogy and intellectual inheritance: (1) the scientific study of societies, often seen as in “crisis”; (2) the modernist faith in progress coupled with the belief that scientific knowledge is a necessary prerequisite of that progress; and (3) the belief that a science of society can guide and accelerate human progress and happiness within the societies that fall within its gaze. The history of sociology is performative proof that it is possible to construct an object of scientific study designated as “society,” and

reflect upon, analyze, categorize, critique, and transform that object. A less charitable view of such a grandiose project for sociology holds that Comte's (and Herbert Spencer's) grand pronouncements for sociology, as Isaiah Berlin (1959/1969) once put it, produced only "huge half-forgotten hulks in the river of nineteenth century thought."

To define sociology as a science of society implies that among the large bibliographic textual output produced by sociologists, not all of it (even under an extended definition of what "science" might be) can be classified as examples of a scientific – i.e., "empirical" – investigation of society, namely as "sociology." Counterintuitively, under this definition, definitions of what sociology might or might not be cannot themselves be considered as instances of sociology. This very entry would be one such instance, thus not an example of sociology under this definition.

The Birth of Sociology

It is within this very definitional and historical paradox that sociology was born. Comte's early vision of what this new social science was capable of achieving included both scientific and reformist/utopian objectives. The utopian world that would be produced by sociology was, for Comte, the final flowering of centuries of progressive intellectual development from the "theological" through the "metaphysical" to the "scientific." To usher in this utopian world, a new order of sociologist-priests would work with the knowledge produced by sociology, as blueprints for the reconstruction of not just Parisian or French or even Western European society, but of something much larger: "humanity." It was, *par excellence*, an example of Western thought of universal application.

Sociology's founding was marked from its very beginning by Auguste Comte's very choice of a term to designate this new scientific discipline. A bastard science, as John Stuart Mill called it (Rosenberg 1953), progeny of the coupling of

the Latin *socius* and the Greek *logos*, Comte's term, *sociologie*, designated its object of study, its ontology, and its corresponding epistemology. It was to be the science – logos – of the *socius*. Yet Comte, despite his pronouncements regarding what this science would be and what it would achieve, never himself produced an empirical scientific study, at least nothing that would qualify for publication as a serious work in a contemporary journal within the profession. The appearance of such an empirical text would have to wait until one of Comte's followers, Émile Durkheim (1858–1917), undertook to produce such a work. One of the first examples of a sociological study as defined by Comte was Durkheim's 1897 *Le Suicide* (with his earlier work on the division of labor a precursor).

Sociology and the Creation of the Socius/Society As an Ontological Object

By the end of the nineteenth century, the ontological object that Comte, Durkheim, and others had charted out, named and constructed through its very naming – *socius* – gained multiple significations in its modern language translations: "Community," *Gemeinschaft*, the "Social Order," more simply, "Society" or *Gesellschaft* (von Wiese 1932). The concrete individual, previously considered in post-Christian thought as a unique biological or spiritual creature, a human being, with a name and biographical life trajectory (and with a unique soul), was reconfigured within this new ontological space as an abstraction, as a product of ideal or material social forces and collective structures larger and more substantial than, and, importantly, more causally determinative than, the empty vessel that was the concrete individual (Comte 1822). Given this newly configured ontological object, the objective of this new science of sociology was to follow the natural scientific methods of observation, experimentation, and comparison to establish universal laws of social phenomena (Comte added the historical method to sociology's conceptual toolkit, signaling an expansion beyond the methods of the natural

sciences). This newly minted method was to accomplish its work of fixing the ontological space of the socius by stripping out what was previously seen as the uniqueness of the individual and his or her private psychological experience, and in its place, creating abstract, scientific objects/types of social phenomena that would then be subject to scientific manipulation and reduction to laws isomorphic with those found in the natural sciences. This newly created ontological object – socius – was as “real” as minerals and physical forces in the natural world and thus should be so studied. As Comte’s follower Durkheim put it, “social facts” should be considered as “things.” The socius was conceptualized as a “*sui generis*,” emergent reality and thus irreducible to any other scientific object in the natural or organic world.

Yet what this new “science” might designate became, and remains, problematic, not least because the very meaning of the term “science” itself was from the very beginning contested. The Comtean conception of sociology and society was almost immediately subjected to critique and revision. What Max Weber (1864–1920) and German sociologists of his generation understood under the term *Wissenschaft* is not what English or French speakers typically understand under the term “science.” Weber argued that a proper study of human action had necessarily to include the subjective meanings that individuals attached to their and other’s behaviors (Schütz 1967), a construction that Comte and other positivists would dismiss as the product of superstitious thinking, more characteristic of the receding metaphysical phase of thought. In that direction, a positive science of the socius would be not just implausible, but impossible.

This initial divide between early sociological thinkers as to what the “Individual” and “Society” meant ontologically and how the socius was to be approached epistemologically has changed over time, but it remains at the center of the discipline of sociology. In this sense, the ontological object of sociology – the socius – and thus sociology itself, has never been fixed in any consensual way and thus remains contested.

This divide has wide-ranging implications for what one might consider to be possible for individuals and/or societies. Presuppositions related to how one conceptualizes social causality as due to (in relative terms), on the one hand, social structural influences and top-down social processes, or, on the other hand, as due to bottom-up, autonomous human subject/individual level phenomena create different conceptions of, and strategies for, actions regarding the possible and the impossible. Notwithstanding this divide, the study of the ontological space known as the socius involves understanding social processes that both unite and divide human beings, unities and divisions that render some projects in life (in the Sartrean sense) possible and render others impossible. The debates generated by the unities/divisions and possible/impossible dialectic have historically been collected under the so-called “Problem of Order” debate – arguably the central problematic of the entire discipline of sociology.

Perusing of this enormous textual output of sociology brings us back to Comte. Across the landscape of contemporary sociology, the goal remains the empirical description of the socius. It is not empirical description *simpliciter* but a particular type of empirical description. It is an epistemology that focuses on and isolates the socius. This is apparent not only in empirical studies, but also in what is called “sociological theory,” the purpose of which is assumed to be either to direct the focus of empirical sociological inquiry, or to be something that empirical studies should contribute to, or to be the subfield wherein the significance of empirical studies is evaluated and synthesized under some larger, umbrella perspective.

Sociology and the Possible

Already within Comte existed the assumption that sociological knowledge is useful, that it can help create or make possible things or conditions that did not exist before, and that it can be used to better our world. Even among those sociologists who eschew politics and argue that the point is to

analyze and describe the socius and no more, something approaching a “pure science,” a term more common in the natural than the social sciences, the question remains: Why would one want to simply represent? What would be the purpose of that? What technical use would pure sociological knowledge, if there were such a thing, permit?

There are two sets of possibilities that sociology might make possible. The first concerns the socius, the transformation of the empirical socius, to make it less unjust, less unequal, less oppressive, and less violent, to transform “the world.”

The second concerns the individual, the transformative potential of sociological knowledge, the possibility that encountering, possessing, and being inscribed by sociological knowledge is transformative, that it can make one a different – presumably better – person.

Possibilities for Another World

When considering sociology as a transformative agent in history, few thinkers have matched the industry or imagination of the discipline’s founder. In three major studies (11 volumes in toto) released to the world between 1822–1857, Comte reviewed in great detail his methodology and substantive vision for sociology as well as its unique positioning as the spiritual authority for the coming utopian world. Comte claimed that after centuries of “theocracy,” the age of “Sociocracy” had arrived, thanks to sociology’s arrival on the historical stage. In Comte’s first major work, his 1822 *Plan for the Scientific Operations Necessary for Reorganizing Society*, he sets out his mission statement for the new discipline of sociology. In that work, Comte made clear exactly what sociology deemed possible and what it rendered impossible. For Comte, sociology revealed that the brief episode in western thought that celebrated the unique individual was quickly receding into the past. His 1822 blueprint for the coming utopia predicated an organic organization of humanity (what else could the *organization* of the socius actually be?) with freedom of thought and popular sovereignty swept away by the inevitable march of the positive science of sociology and the elevation of

the sociologist to the position of spiritual guide to humanity. As Comte put it: “In astronomy, physics, chemistry and physiology there is no such thing as liberty of conscience [thought]; that is to say everyone would deem it absurd not to place confidence in the principles established for these sciences by competent thinkers” (Comte 1822). In this new conception of the socius, the individual realizes a freedom unknown to the *philosopher* and others still stuck in the metaphysical phase of thought. In Comte’s borrowing of Hegel’s paradoxical notion, Comte claimed that “Freedom is the recognition of necessity.” In such a world, the possibilities for individual creative thought and collective action recede in proportion to the expansion of the socius’ capacity to organize collective forms of life. In this top-down, elitist conception of the organization of society, fanciful notions of an egalitarian society are swept aside and in its place the elevation of Authority, presumably legitimated and accepted by all, and recognized as the inevitable consequence of the organic conception of society as revealed by the new science of sociology.

The ‘sovereignty of the people’ tends to dismember the body politic by placing power in the least capable hands. . . and the ‘right of private judgment’ tends to the complete isolation of thinkers by investing the least enlightened men with an absolute right of control over the system of ideas conceived by superior intellects for the guidance of society. (Comte 1822)

As seen in Comte’s work, the mission statement for sociology goes far beyond a mere academic rendering of the details of an already existing, fully specified world. Rather, the very ontology of the world is to be, should be, transformed. Here, the classic statement regarding the possibility of social thought to change the world is Marx’s Eleventh Thesis on Feuerbach: “The philosophers have only interpreted the world; the point, however, is to change it.”

In this vein, sociology’s answer to the question “Is another world possible?” is unequivocal. It is, and, further, sociology can aid us in reflecting on what those imagined other worlds might be, and how we might actively intervene in

the functioning of the *socius* to achieve a better world. While understanding inequalities and injustices that interpenetrate social class, race, gender, and sexual politics are not the only concerns of the discipline; they have come to constitute the bulk of contemporary empirical research and theorizing. Understanding how these inequalities are reproduced, it is hoped, opens possibilities to create an alternative world. How these concerns intersect with the individual and their relationship to necessity and/or agency or possibility is the focus of C. Wright Mills' (1916–1962) contribution to the understanding of the *socius*.

Sociology As Personal Transformation, As Bildung, and As Social Therapy

The classic statement on sociology's possibilities is Mills' *The Sociological Imagination*. What Mills called "the sociological imagination" allows us, he argued, to temporally locate ourselves within the arc of world history and to locate ourselves within the topography of the society we inhabit. It is in the first chapter of *The Sociological Imagination*, "The Promise," where Mills summarizes the benefits a sociological imagination might provide to those who have come into possession of such an imagination. The promise of sociology is that it will help us transcend our small, parochial, local worlds and their attendant limited private experiences and allow us to understand those worlds and ourselves in the context of events of world historical importance. We will be transformed into cosmopolitans; we will come to understand that our very selves are "points of the intersections of biography and history within society" (Mills 1959).

While Mills' own summary of his book stressed the relationship between history and biography, this was supplemented with the frequently cited observation that: "Perhaps the most fruitful distinction with which the sociological imagination works is between 'the personal troubles of milieu' and 'the public issues of social structure'" (Mills 1959). The sociological imagination will help us, Mills believed, to see that

what we took to be our private troubles – unemployment or divorce, for example – are neither simply nor entirely personal problems but are related to, or are instances of, larger public issues.

It is an imagination, Mills suggested, that can lead to our fighting to change the world by understanding and confronting the ubiquitous inequalities and injustices that surround us. It can also result in our own personal transformation. Mills suggests that with the realization that we all are, in many ways, outsiders in our own societies, strangers to each other, and even to ourselves, we can come to understand the social relativity of all social life and hence recognize the opportunity we all have to become someone other than whom we have come to know as our own self. With such an awareness can come a shock of recognition: People "feel as if suddenly awakened in a house with which they had only supposed themselves to be familiar. . . . Their capacity for astonishment is made lively again. They acquire a new way of thinking, they experience a transvaluation of values: in a word, by their reflection and by their sensibility, they realize the cultural meaning of the social science" (Mills 1959).

While disorienting, Mills argues that such an awareness can lead to a transformation of one's self-consciousness and a reassessment of one's life; in short, it can lead to personal transformation. The past and the future become alive with possibilities. As Mills put it, "we do not know the limits of man's capacities for supreme effort or willing degradation, for agony or glee, for pleasurable brutality or the sweetness of reason." This is hardly a world that the self-confident founder of sociology could possibly have imagined.

Aalborg University, Aalborg, Denmark

Abstract

This entry provides a selective overview of sport studies that involve notions of the possible and demonstrates its developmental, experiential, and performative potentials. First, the entry outlines different perspectives on sport performance in competitive interaction sports that exhibits the importance of engaging with the possible during the game. It continues with a brief review of existential perspectives that see athletes as possible selves. Last but not least, it highlights sport coaching frameworks that may be used to help athletes engage with the possible. The entry is finalized with a call for more empirical research on the possible in sport.

Keywords

Sport · Athlete · Creativity · Possible · Exploration

The spirit of sport is forcefully embraced by the Olympic motto of “citius, fortius, altius” (i.e., faster, higher, stronger) which refers to the ethical, honest, and committed perfection of personal talents in order to excel in performance, to courageously and respectfully compete in solitude or teamwork, and to have fun and participate in sporting activities with friends. Critically discussing the humanistic potential of the Olympics from an existential perspective, Konstantinov (2017) conceptualized Olympism as a “creating creation” (i.e., similar to the arts), an artifact created by humans to create something in humans. In this regard, the Olympics was portrayed as a creative drive, as a site for human self-realization, self-perfection, self-overcoming, and overstepping the boundaries of oneself. Hence, sport is tightly connected to the possible, with athletes striving to stretch their potential to its limits. As Anderson, (2001) conveniently pointed out, the sporting world “is full of exemplary cases in which a sport or practice is openly transformed by an athlete who takes up the sense of possibility and goes to work on realizing novel ways of participating or performing” (p. 144).

Paradoxically, however, with political and cultural pressure to win medals, sport is often more associated with strenuous training and repetition to perfection than with playful exploration of new positions, perspectives, and possibilities. In terms of sociocultural influences, acculturation processes of sports are “driven by explicit and socially-imposed convergence to a common optimal performance model (e.g. a putative “champion” model or a classical technique),” which constrain the exploratory behaviour of the athlete and thus “play a conservative role” regarding their novelty- and idiosyncratic tendencies, aligning them in a “collective direction” (Hristovski et al. 2011, p. 181). As argued by Bar-Eli et al. (2006), many contexts of sport suffer from instrumental rationality due to the principle of “maximization through optimization” which emphasize effectiveness and assumes that a universally optimal solution exists for a particular problem (e.g., in a specific game situation). In this regard, several studies (for overview, see Cushion

2013) have shown that sport coaches tend to reject innovative sport-pedagogical approaches. Some prefer to stick with the safe and tested means, and others superficially adopt the ideas that confirm their beliefs and verify their expertise. Consequently, the players do not get to experience new approaches. In turn, these overly socialized players may both prefer and expect traditional coaching and therefore resist alternative approaches. As argued by Occhino et al. (2014), a coach's ideology may "shape an athlete's view of their sport participation – psychologically, emotionally, and physically" (p. 404). Hence, it determines their learning preferences and the eventual outcomes of their sport participation.

From these initial considerations, there seems to be poor conditions to engage with the possible in sport, but doing so could have both developmental, experiential, and performative implications. Herein, the aim of this entry is to provide an overview of sport studies that can contribute with relevant perspectives for the study of the possible, particularly drawing on the field of sporting creativity. This account is necessarily selective given the boundaries of this encyclopedia and especially the richness of research interests readily associated with the topic of the possible (Glăveanu 2018). The entry starts by outlining different theoretical perspectives on sport performance that exhibits the importance of engaging with the possible in the heat of the game. It continues with a brief review of existential perspectives that see athletes as possible selves. Last but not least, the entry highlights a few sport coaching frameworks that involve notions of the possible. The entry is concluded with a call for more empirical research on the possible in sport.

Sport as a Sphere for the Possible

This entry focuses on competitive interaction sports (e.g., ice hockey, soccer, and basketball), where creativity (and thus engaging with the possible) is vital to successful performance (Rasmussen 2019). These dynamic sport

disciplines have a strong prevalence for creativity (rather than imitation) due to frequent occurrences of unique, open-ended, and unexpected situations, which require anticipation, adaptation, flexible decisions, and new solutions, and since the rival can be surprised by a variety of original solutions and strategic methods (Ovens and Smith 2006). Further, the possible is inherent to the dynamic systems theoretical approach to creativity in sport. From this perspective, sports are seen as disordered, complex systems characterized by multistability, which refer to the coexistence of multiple possible solutions in every situation (Hristovski et al. 2012). At any moment, each player has access to different degrees of freedom (i.e., sets of functionally appropriate possibilities), which are continually changed by the co-adaptive dynamic actions of teammates and opponents. Matches in these complex games are highly unstable and varied processes, where the players on the two teams aim to create poor conditions for their opponents and favorable ones for their teammates. While stereotypical playing styles gradually loses their efficiency (Aggerholm et al. 2011), this can be achieved by being sufficiently unpredictable for opponents and predictable for teammates. Such an uncertain environment requires the players to continually adapt to changing situations and to be open to and utilize unexpected and novel possibilities.

For Aggerholm et al. (2011), the essence of soccer (i.e., Association football) is that the players constantly have to engage in, relate to, and adapt to open, indeterminate, unfolding social situations. The game is characterized by a high degree of contingency, due to its "dynamic social configuration with a tension-balance relation" (Aggerholm et al. 2011, p. 347) between the two opposing teams, who simultaneously try to unbalance and resist each other. This counterproductive relationship (i.e., opposition with continuous responses and counter-responses) shape the possible courses of action for the player and highlights the improvisational element of invasion games (Tanggaard et al. 2016). Drawing on Bachelard and Merleau-Ponty, Edgar (2015) characterized soccer as a "contest over space" (p. 164)

and portrayed soccer players as “poets of space,” who creatively imagine how different places on the pitch can be created and inhabited in order to enable their own capacities to flourish and their opponents’ to diminish. In this regard, Aggerholm et al. (2011) suggested “pretention” as a concept for the “deceptive rush into the future” (p. 355) which is required to perform creatively in soccer (i.e., do a feint); in pretence, the opponents’ intentions and meaning horizons are modelled (e.g., through seduction; building up their expectations) and the acting player’s future possibilities are created. This requires distinctive kinds of bodily and intersubjective awareness. To always be two steps ahead and to plan luring, deceptive acts, the player must be absorbed in their opponent(s) – they need “awareness of the relational situation” (p. 350) and openness to the unfolding possibilities in order to “take the right initiative at the right time” (p. 352) and win the duel.

Drawing on Thoreau’s transcendentalist concerns about living an *over-civilized* or mechanical life on the one hand, or an *under-civilized* or savage existence on the other, Anderson (2001) argued that sport offer a lived “sense of sheer possibility” (p. 143), which counteracts the sedating powers of everyday life, awakens people to their human agency, their potential for transformation, and their possibility of living an “intrinsically meaningful life” (p. 141). Anderson (2001) exemplifies how this feeling of energetic lightness comes in anticipation of a basketball game when stepping onto the court:

The court seem to respond to the players’ anticipation and become a site of freedom. They burst on the court almost as if they were dancers [...] the felt possibility wrenches us from the domineering social world of the everyday. If only for a few minutes, we are, as Thoreau puts it, ‘returned to our senses’ [...] We know – because the game or the practice lets us feel it – that we have a capacity for more, even if we’re not precisely sure what that ‘more’ is. (p. 143)

Hence, Anderson (2001) argued that most people live as if they are blind to their creative possibilities, but creative experiences in sport can them recover this vital aspect of their humanity. Sport enable its participants to face the world in novel

ways and provide them with “the room to create” (p. 144), to discover new ways to perform or participate. From this perspective, sport is a “site of risk in context, of spontaneity within constraints” (p. 142) that enable people to live as a *frontier*, that is, a dynamic, free, and undogmatic existence on the border between an over- and under-civilized life.

Equivalent ends can be drawn from Conill Sancho’s (2016) and Inglis’ (2004) elucidations of Gasset’s *ratiovitalism*, where life is basically understood as a “creative experiment” (Conill Sancho 2016, p. 418). In order to live, humans do not adapt to the medium but actively adapts it. According to Inglis (2004), this creative power is particularly inherent in sports, and therefore, it is “in the pursuit of sportive activities, not instrumentally guided labor, that man truly finds contentment” (p. 86). From this view, sports are not limited by utilitarian perspectives, but opens a “superior form of human existence [...] a festival and creative meaning of life” (Conill Sancho 2016, p. 416). Accordingly, drawing on the latter perspective, it could be argued that if sports do not allow its participants to adapt the medium (that is, to be creative), then they will cease to exist.

Athletes as Possible Selves

In his editorial on *The Possible as a Field of Inquiry*, Glăveanu (2018) explored different perspectives on “the possible self” and argued that human beings “exist, at all times, between the ‘here and now’ of their concrete life situation and the then and there of creativity, wonder, and imagination” (p. 522). The idea to treat athletes as possible selves is not new in the sport literature. For example, Heidegger’s notion of the “Dasein,” that describes the human being’s way of existence as being open to their own being, to others and the world, and to future possibilities (in order to live authentically, rather than falling to and accepting the traditional views and ways of “das man”), has been widely applied and discussed in the philosophy of sport (Lopez

Frias and Gimeno Monfort 2016; Martinková and Parry 2016). In a recent paper, extending Heidegger's idea of how Dasein either deal with the environment in a practical ("Zuhandenheit") or theoretical ("Vorhandenheit") mode, Breivik (2020) discussed the ontology of the sporting human being, focusing on how it – as "homo movens" and "homo ludens" – playfully explore and experiment with its environing world and itself. Through explorative play, the sporting being builds internal models of the interactional possibilities of its bodily being-in-the world in a particular sporting context (individual, encounter, team, or nature sport). According to Breivik, these types of sport involve the fundamental question of play (i.e., "What can I do (with and through my body)?"), but also pursuits of goal-directed questions of perfection (i.e., "What can I do at my best?"). Yet, this self-testing element (which can lead to innovations) is different in encounter sports and especially in team sports since there is a contest, that is, an I-You or We-They relation. Being part of a team and taking a certain role with particular tasks and obligations, to some extent limits the freedom of the sporting human being since efficient collaboration is needed to win (Breivik 2020).

Using Nancy's ontological notion of "being-with" (i.e., a foregrounding of Heidegger's notion of "Mitsein," i.e., that meaning-making is basically relational since we are thrown into the world with other beings), Hardes and Hogeveen (2016) highlighted that sport performances are conditioned and constructed by the particularities of the athlete's lives, constituted through their various relations with others, and with the objects and technologies others have given agency to. From this perspective, athletes are not understood as fixed, solitary, and self-enclosed subjects who strive for experiences that fulfil repeatable and unchanging criteria of flow (i.e., traditional accounts of flow), but as open and unique singularities that are in constant flux and always forge new relations with others and the world: "singular experience is always an iteration that is an opening towards the other and new ways of being in the world" (p. 287). Based

on Csikszentmihalyi's idea that flow states constitute spaces to expand and transcend the self, and lead to a feeling of having pushed forward boundaries of our being, flow is understood as an opening out of the athlete's self – "it is about excesses, ways of being anew, becoming other, and doing so creatively" (p. 287). As Hardes and Hogeveen (2016) highlight, sport participation "give us the opportunity not only to experience our bodies in new ways definable to the practice, but also to exceed these bodily experiences in new and different ways" (p. 287). From this perspective, it is unethical and potentially harmful when coaches push athletes to states of skillful coping that cuts off the opportunity for seeking out new possibilities and creative experience. Such strivings may not only entail dogmatic coaching practices and discouraged athletes, but also have a negative and limiting impact on how the athletes think they ought to experience their sport (Hardes and Hogeveen 2016). Athletes should be freed from mechanical procedures and desires for external perfection, and instead be given opportunities to explore novel possibilities, in order to transcend themselves and experience their body in new ways definable to the sporting context.

An ethics of flow would not be found in the seeking out of repetitive mechanistic experiences that turn us into clones of ourselves or cyborgs; the playfulness of a flow-like experience comes from noting the immanence of life and the relatedness of the self to the world and to others. (Hardes and Hogeveen 2016, p. 287)

While the abovementioned contributions focus on describing athletes' natural openness to the possible, other scholars have that specified particular existential attitudes may be beneficial to engage with the possible (and thereby enhance performance) in sport. For example, Campos (2014) described spontaneity as a "freshness in our way of approaching the activity" (p. 58) which revitalizes the game by changing and renewing the courses it may take, preventing it from being habitual and ordinary. Drawing on the work of Peirce, he also defined it an instinctive capacity for unforeseen

and unscripted actions, and a lively, fresh, and playful attitude manifested as “exploration of the unexplored” (p. 58). Along similar lines, Hopsicker (2011) argued that an important benchmark for becoming a sporting genius (i.e., innovative performers who test current conventions and form new standard models) is to adopt a risk-taking attitude, which regards a “comfortable attitude of not knowing what will come next” (p. 21). Further, Aggerholm and Ronglan (2012) performed an existential analysis of humor as a habitual relation to the world which includes considerations of the humorist athlete’s capability and desire to “point to the possible” (p. 340). Among more, they argue that humor can help athletes spot and challenge unsustainable conventions, norms, and contradictions, enable a playful approach to the game, and be a vehicle for motivation, learning, and creativity.

Through a *playful distancing* the humorist transcends the borders of the self and the actual world, which allows the player to risk losing himself in the activity and thereby gaining new possibilities of performance. It challenges the real and opens new possibilities. [...] The humorous player has a drive for curious experimenting with the given and the ability to see situations as possibilities and not just the facts. (pp. 339–340)

This playful attitude of humor illuminates how humoristic athletes turn towards the possible by looking at the ongoing game situation from an intentional distance. Specifically, this part of their analysis elaborated Kretchmar’s (1982) notion of abstract thinking as “distancing” oneself from the surrounding environment (i.e., the object of consciousness), which enables the athlete to make new connections between seemingly unrelated phenomena in the game. Seeing possibilities, the humorist has a potential to make a qualitative difference in the game (Aggerholm and Ronglan 2012).

Nurturing the Possible in Sports

While several scholars recognize the need to engage with the possible in the performance

contexts of competitive interaction sports as well as the importance of treating athletes as possible selves (both on and off the pitch), there is a scarcity of studies that genuinely embrace these aspects by offering practical resources (e.g., coaching principles) to help athletes engage with the possible. Nevertheless, two sport pedagogical frameworks are worth highlighting.

First, a cornerstone of *nonlinear pedagogy* is that manipulation of task constraints (e.g., rules, instructions, cues, and the game configuration) and environmental constraints (e.g., sociocultural and physical influences) is a key to facilitate explorative (and creative) behavior where the athlete search for novel performer-environment configurations (Chow et al. 2011). Nonlinear interactions between these types of constraints and the player’s unique psychological, morphological, and physiological makeup (i.e., personal constraints) shape the player’s landscape of affordances, a “hypothetical workspace” which contain all the action possibilities in the given situation (p. 191). Hence, the continuous manipulation of constraints enhances the chance of qualitative reorganizations (i.e., components coupled in novel ways) and action insight (i.e., discovery of atypical, functional opportunities) in the movement system. This can be facilitated by coaches by relaxing constraints, so more solutions are possible, habitual actions are suppressed (Hristovski et al. 2012), or by dampening or amplifying sociocultural constraints that are usually overemphasized or deprioritized in the particular context (Vaughan et al. 2019). As Vaughan et al. (2019) propose, teams limited by intrateam competition may benefit from activities designed to dampen this influence (e.g., a task requiring collaboration and teamwork), and generally, to help their players discover new action possibilities, coaches could design tasks focusing on certain abilities flourishing in other sociocultural movement practices (e.g., samba, capoeira and other sport cultures). Finally, the exploratory behavior can also be controlled by players able to suppress habitual actions and purposefully engage in creative self-

reorganization of task and environmental constraints (e.g., altering interpersonal distance), to open and explore space-time windows for novel actions (Hristovski et al. 2012). Among others, the ability to do so depend on the openness of both the athlete and of the practice forms and playing style in their environment (Vaughan et al. 2019).

Second, the *situated model of creative actions in sport* locates the openminded and playful exploration of novel and unusual action possibilities at the heart of the creative process (Rasmussen et al. 2019). This work captures the tension between the possible, the actual, the self, and the other. Based on Dewey's educational philosophy, it also illustrates how engaging with the possible may enhance the players' growth (e.g., in terms of developing their initiative in applying their capacities to novel aims) and expand and enrich the players' experience of their sport. Extending this perspective, Rasmussen et al. (2019) outlined four components that affect the athlete's horizon of action in any given situation, that is, the range of action possibilities that are open to be explored: *normativity, materiality, intentionality, and capability*. These components are defined below and exemplified with a study demonstrating its role in terms of affecting the players' capacity to engage with the possible.

Normativity refers to cultural norms, values, procedures, coaching standards, and social expectations that determine the approved action space, or the range of appropriate actions, and lead to certain kinds of actions being encouraged and rewarded at the expense of others. For example, application of *The Creative Soccer Platform* (i.e., the didactic principles of task focus, parallel thinking, horizontal thinking, and no experienced judgment) may (momentarily) establish an autonomy supportive, judgment free, and playful training environment where the players are more confident in originating and attempting new and abnormal actions (Rasmussen and Østergaard 2016).

Materiality regards physical (e.g., objects; field shape and surface) and conceptual (e.g., symbols, principles, agreements, and templates) action

resources. For example, Tanggaard et al. (2016) argued how changes in handball material from natural to synthetic leather and the introduction of resin afforded the advance of wing players' remarkable ways of shooting. In turn, these trick shots contributed to innovation in handball. Since the material changes allowed the attackers to release the ball in new ways, it also enabled them to interact with their teammates in new ways. These new possibilities for the attackers also changed the conditions for the defenders who had to come up with countermeasures and new ways to cooperate in their defensive zones (Tanggaard et al. 2016).

Intentionality is an action orientation towards specific aspects of the environment (e.g., have fun with friends, imitate famous players, avoid mistakes, or satisfy others). For example, in a social priming experiment, Furley and Memmert (2018) showed that amateur soccer players performed better on a soccer-specific divergent thinking task after being exposed to the names and images of creative soccer experts (e.g., Lionel Messi) and writing down their characteristics.

Capability regards the players' action capacity which is not only comprised by their bodily abilities (e.g., physical skills, technical skills) but also their emotional attitude towards – and their subjective experience of – their own body, which determine what they believe they can do with it (or through it) in the given situation. For example, Moraru et al. (2016) argued that the players' motor ability to perform the imagined actions may limit their originality in divergent doing tasks. In terms of exploring the possible, this is especially a problem if there are high demands for appropriateness (Rasmussen 2019).

The situated interaction between the four abovementioned components define the player's usual actions, or their habitual action repertoire, in a given situation. From this perspective, creativity regards transcending the usual. In order to help players do so, coaches may inter alia relax normative expectations (e.g., momentarily preferring quantity over quality), form novel material conditions (e.g., play with

another kind of ball), and encourage the players to engage with unfamiliar intentions (e.g., play to explore, rather than to win at all costs). Such initiatives could be implemented in connection to designing particular tasks where the players cannot rely on habitual action repertoires but need to change their perspective and explore unusual action possibilities in order to play the game (Rasmussen et al. 2019).

Conclusion

This entry explored sports as a domain for the possible and highlighted a selective range of sport studies that include relevant perspectives regarding the possible. First, competitive interaction sports were considered as spheres for engaging with the possible. Both a developmental and performative perspective, there is little sense in maintaining the actual in the complex and open-ended performance contexts formed in these disciplines. Second, athletes were portrayed as possible selves, as humans who are fundamentally open to other ways of being in the world and both have a need for and capacity to interfere with and shape their environment. As shown during this entry, engaging with the possible in sport may have a variety of developmental, experiential and performative implications. In this regard, the entry listed particular existential attitudes that helps the athlete engage with and explore the possible. Unfortunately, this may be a rare phenomenon in competitive interaction sport – especially in high-performance contexts – which are concurrently portrayed by disciplinary and conforming approaches, instrumental use of the athletes' bodies, and suppression of spontaneity in defense to territorial interests of the team (Cushion and Jones 2014; Manley et al. 2012). In these contexts, fruitful creative inquiries are often stalled by disempowering and repressive practices, where coaches are perceived as being solely responsible for their athletes' development and believe that optimal performance models exist. Hence, there is a large potential in helping coaches understand the value of engaging with the possible. Recently, an attempt to do so through action research was done

with varying success (Rasmussen et al. 2020). Third, the entry outlined two sport pedagogical approaches that may serve as alternatives to traditional approaches since they offer practical resources that may help coaches design tasks where their athletes need to explore novel and unusual action possibilities. Finally, as evident in the entry, most sport studies that involve relevant notions of the possible are of a theoretical and philosophical kind, and do not involve the perspectives of the actors involved on the pitch. Thus, this entry stresses importance of conducting more qualitative and contextualized research on the possible in competitive interaction sport.

Abstract

Alfred North Whitehead (1861–1947) was a prominent multidisciplinary figure, whose intellectual interests extended over mathematics, philosophy of science, history of science, education, religion, and metaphysics. The common thread to be found in Whitehead's work across diversified disciplines is his quest for universal connectedness, which can be found in all his theoretical frameworks. In mathematics, Whitehead pursued a generalized theoretical framework based on symbolic logic, along with Bertrand Russell. In the philosophy of science, Whitehead stated that for a natural phenomenon to exist, space and time must enable interconnection, without falling into the trap of ideal point-like abstractions, and hence of scientific materialism. In the philosophy of education, Whitehead proposed the development of interwoven literary, scientific, and technical curricula, all pointing to the single ultimate subject: life. In religion, Whitehead saw God as both primordial and consequent, giving original input to the process of organic evolution of the universe and then judging its development with benevolence. In metaphysics, Whitehead elected creativity as the ultimate principle, which brings together the multitude of the many into the uniqueness of the ever-transforming one. Importance and expression are, respectively, defined by Whitehead in view of their immanence of the infinitude into the finite and of the finitude into

the infinite. Process philosophy is arguably Whitehead's main contribution, positing a cosmological view on the universe dominated by creativity, potentiality, possibility, connectiveness, and teleological value. Whitehead's legacy is finally briefly discussed with reference to theology, eastern philosophy, quantum physics, sociology, and creativity studies.

Introductory Notes About Whitehead

Alfred North Whitehead (1861–1947) is considered to be a prominent multidisciplinary figure in the scientific and philosophical panorama of the twentieth century, with intellectual interests extending over mathematics, philosophy of science, history of science, education, religion, and metaphysics. The evolution of his fields of interest in the course of his lifetime can also be linked to his academic trajectory that can be roughly divided into three periods, respectively, associated to his assignments in Cambridge (UK), London (UK), and finally Cambridge (Massachusetts, USA). Whitehead was born in Ramsgate (UK) on February 15, 1861; after receiving his degree at Trinity College in Cambridge, he became a professor there from 1884 to 1910, where mathematics was his primary field of work, with a strong emphasis on symbolic logic. In 1910 he moved to London to join the Imperial College, where his concerns for philosophy and history of science gained momentum, always in parallel to a continued interest in mathematics and mathematical physics, spurred by the contemporary rise of relativity theory and quantum physics. In 1918 Whitehead was elected dean of the Faculty of Science at the University of London, and this position gave him the chance to develop his well-defined philosophy of education. In 1924,

when he would have been forced to retire by British law, he took a position as professor of philosophy at Harvard (Cambridge, Massachusetts). The peculiarity of his academic evolution appears clearly in his own words (Whitehead and Price 1954/2001, p. 146):

All my life [...] I had been a lecturer in mathematics. At the age of sixty-three in 1924, I came to Harvard to lecture on philosophy for the first time.

This final period of his life was ripe with results in metaphysics and religion: the philosophical framework constituting Whitehead's main contribution, identified as *process philosophy*, emerged here in all its breadth. This is where the concept of the possible, potential, and possibility acquires definitive substance. Alfred North Whitehead died in Cambridge (Massachusetts) on December 30, 1947.

Whitehead's Multidisciplinary Contributions

Whitehead was a prolific writer who produced nearly 30 books, notwithstanding the fact that his approach to the transformation of ideas into written text was quite unique (Whitehead and Price 1954/2001, p. 146): "I do not think in words. I begin with concepts, then try to put them into words, which is often very difficult." If a common thread were to be found in Whitehead's work across diversified disciplines, this would have to be the quest for universal connectedness, which can be found in all his theoretical frameworks. In the following, Whitehead's main contributions to the fields of mathematics, philosophy of science, philosophy of education, religion, and metaphysics are synthetically described, in this order. More extended information is provided, in particular, by Desmet and Irvine (2018).

In mathematics, first in his *A Treatise on Universal Algebra with Applications* (Whitehead 1898), and later, collaborating with his former disciple Bertrand Russell, in the famous trilogy entitled *Principia Mathematica* (Whitehead and Russell 1910, 1912, 1913), Whitehead pursues a systematization of the entire field of mathematics

through the use of symbolic logic as a universal approach. It is to be noted that, although the two authors collaborated closely in the development of this monumental endeavor (yet unfinished, as a fourth volume would have been foreseen), their vision on the ultimate significance of logic diverged. While Whitehead saw mathematical logic merely as an instrument to guide intuition and generalization into patterns, Russell held an objective to show the supremacy of logic over other forms of mathematical thought. In this view, Whitehead was closer to his contemporary Henri Poincaré (Corazza and Lubart 2019) than to Russell. Later on, the layout of Whitehead's process philosophy, based on the foundation of a world composed of interweaved processes and events and in which isolated objects cannot exist, resulted to be in complete opposition to the doctrine of logical atomism theorized by Russell.

Considering Whitehead's contributions to the philosophy of science, one of his first works entitled *An Enquiry Concerning the Principles of Natural Knowledge* (Whitehead 1919/1982) already contains the initial elements of what he would develop as a harsh critique of Newton's notion of dimensionless points and time instants, a notion upon which classical physics is fundamentally based. In Whitehead's mind, in order for a natural phenomenon to exist, space and time must enable interconnection, without falling into the trap of affording a status of reality to ideal point-like abstractions. In other words, instead of considering space and time as dimensions that afford a disconnected description of reality, the emphasis should be placed on the ways in which all essences are ultimately connected. Possibilities stem out of interconnections. It should be underlined that Whitehead derived these positions not from abstract thought but by observation, adhering to his intuitive grasp of nature. In this sense, his approach to the philosophy of science could be classified as evolutionary naturalist. Interestingly, Whitehead recognized in Leonardo da Vinci a forerunner in the observation of nature as a means to scientific understanding (Northrop and Gross 1953, p. 401):

Perhaps the man who most completely anticipated both Bacon and the whole modern point of view was the artist Leonardo da Vinci, who lived almost exactly a century before Bacon. Leonardo also illustrated the theory which I was advancing in my last lecture, that the rise of naturalistic art was an important ingredient in the formation of our scientific mentality. Indeed, Leonardo was more completely a man of science than was Bacon. . .

Several years later, in *Nature and Life* (Whitehead 1934/2011), Whitehead would confirm this point of view but also extend his critique to the pure sense-based empiricism of Hume, which to Whitehead is also not capable to accommodate and explain the visualization capabilities of the human mind. While Whitehead recognizes that both Newton and Hume proposed valid descriptions within the limits of their assumptions, both omitted the intuitive mode of understanding. On the other hand, the nineteenth century had also seen the rise of the theory of electromagnetism, based on the fundamental results provided by the solutions to Maxwell's equations. The concept of electromagnetic fields, according to which a source of an electromagnetic phenomenon impacts the entire space without any a priori limitation, appeared to Whitehead as the perfect conceptual model to counter Newton's scientific materialism of isolated things. The universe should be thought of as a field of forces, in which every point influences every other point without pause. For Whitehead this was the way to overcome the "fallacy of single location" he attributed to Newton, that is, the idea that nature can be described as a collection of self-sufficient isolated agglomerates of matter in specified positions at specified times. In *Science and the Modern World* (Whitehead 1926a/1967, p. 91), Whitehead advances the explicit proposition that the adoption of the field-based approach entails the abandonment of "simple location [as] the primary way in which things are involved in space-time. In a certain sense, everything is everywhere at all times." It could be argued that the subsequent development of process philosophy was fundamentally inspired by the lessons Whitehead learned about electromagnetism, as exemplified in *Nature and Life* (Whitehead 1934/2011), where he discusses how the

concepts of activity and process are the fundamental building blocks, because nature is a theatre where ever-changing activities play interrelated parts in one universal process and where it is not possible to identify (if not through an approximation) self-contained activities in limited regions of space.

Even when Whitehead was burdened by administrative responsibilities in his role as Dean of the School of Science at the University of London, he never stopped producing original thought. Indeed, these were the years in which Whitehead's philosophy of education was developed, based on the idea that the only subject matter for all education is one: life itself, in all its interrelated ramifications. Therefore, in the field of education, his idea of universality takes on an epistemological declination, whereby literary, scientific, and technical subjects should be interwoven in the design of all educational curricula, as discussed in *The Aims of Education and Other Essays* (Whitehead 1929a). An education system should contain all three curricula, the literary, the scientific, and the technical, but each one should contain elements of the other two, in a sort of beneficial cross-illumination. Further, for Whitehead the mind of a student should never be seen as a box to be filled with chunks of knowledge, alien ideas, or scraps of information. Rather, it should be stimulated in its growth, in a similar way as a living organism would develop under the inputs of the surrounding environment, following a natural "rhythm of education" (Whitehead 1929a). This rhythm consists essentially of repeating cycles of three fundamental phases of a periodic process: in the first phase of "romance," a subject should be freely explored, facilitating all possible occasions for awe and wonder. Once the curiosity level has built up, the phase of "precision" must be opened, in order for the student to acquire methodologies, techniques, and detailed knowledge in a disciplined way. But this is not the end; once mastery of the discipline has been acquired to a sufficient level, then a third phase of "generalization" should be facilitated, to allow the formation of interdisciplinary associations, through the application of domain-specific concepts to domain-general questions. It is interesting

to note the similarity of this cyclic educational approach to the modern concept of agile development of software (Martin 2002). Whitehead's critique of classic educational approaches, in particular for mathematics, is that teachers typically omit phase one and never reach phase three, leaving the student with a collection of aridly disconnected notions. On the other hand, it could be argued that a Montessori approach (Montessori 2013) focuses primarily and successfully on the romance of phase one but may come short at developing precision and generalization. Whitehead's approach appears to provide the well-designed balance needed to achieve thoughts of high quality, enriched by "receptiveness of beauty and humane feeling" (Whitehead 1929a, p. 1).

Apparently, Whitehead's concern for morality and religion did not emerge explicitly in his works until his transfer into the United States, even though the fact that his father Alfred was a reverend might allow presuppositions about his implicit concern for these subjects. Indeed, his philosophy of science was completely devoid of issues of spirituality or morals. But when time was mature, Whitehead's process philosophy was conceived to include spiritual matters as a never-ending search, as portrayed in *Science and the Modern World* (Whitehead 1926a, pp. 191–192):

Religion is the vision of something which stands beyond, behind, and within, the passing flux of immediate things; something which is real, and yet waiting to be realized; something which is a remote possibility, and yet the greatest of present facts; something that gives meaning to all that passes, and yet eludes all apprehension; something whose possession is the final good, and yet is beyond all reach; something which is the ultimate ideal, and the hopeless quest.

However, Whitehead always maintained a clear distinction between the ideal vision of religion described above and its use by mankind, which can reach extremes of good and evil. While religion maintains fundamental importance in being transcendent, in *Religion in the Making* (Whitehead 1926b/1996), he clarifies that the history of religions is unfortunately rich of horrors, including human sacrifice, cannibalism, hatred, war, and bigotry. Still, religion must be

considered as a force with upward trend justifying an optimistic view of the future, despite its cycles of fading and resurrection. Perhaps the most important aspect of Whitehead's contribution to religion is his dipolar definition of God, which can be found in *Process and Reality* (Whitehead 1929b/1978): God is both primordial and consequent. The primordial God is the necessary entity that gives the original input to the process of organic evolution of the universe, without predetermining it. The actual entities and the actual occasions maintain a form of freedom, while God tenderly presents ultimate values and operates to persuade for their pursuit. Then, God is consequent in its judgment of the world, which can only take place if freedom has been granted to the universe, allowing God to tenderly save the world by offering its vision of truth, beauty, and goodness.

Arguably, Whitehead produced his works of highest impact in the field of philosophy and in particular of metaphysics, where all his contributions to mathematics, science, education, and religion find a final and coherent systematization. His philosophical production was based primarily on the transcription of cycles of lessons he held. While *Science and the Modern World* (Whitehead 1926a/1967) was based on the prestigious Lowell Lectures at Harvard, his major work *Process and Reality* (Whitehead 1929b/1978) was derived from the Gifford Lectures at the University of Edinburgh (1927–1928). These two books were conceptually completed in a sort of trilogy by *Adventures of Ideas* (Whitehead 1933/1967). Not surprisingly, Whitehead held strong positions against all forms of disconnection into dichotomies and in particular against the bifurcation between the objectivity of the world of matter of fact and the subjectivity of the world of moral, aesthetic, and religious values. Integration of all disciplines into one cosmology was perhaps his main concern. This harmonization should embrace the abstractions of both science and art, morals and religion, and poetry and mystical visions. Central to this vision of the universe is creativity, which is considered by Whitehead as the ultimate principle of metaphysics, bringing together the multitude of the many into the single

ever-changing unity. Creativity leads to potentiality and possibility, as pure potentials are “eternal objects” the realization of which in the world become the “actual objects.” The essential elements of Whitehead’s process philosophy, drawing from both *Process and Reality* (Whitehead 1929b/1978) and *Modes of Thought* (Whitehead 1938/1968), are discussed next.

Whitehead’s Process Philosophy

Process and Reality (1929b/1978) is undoubtedly Whitehead’s major work, containing all the fundamental conceptual elements of his process philosophy, a cosmological view on the universe dominated by creativity, potentiality, possibility, connectedness, and teleological value. All forms of life are interpreted as expressions of organisms, a term which is endowed with an extended applicability, encompassing also physical systems of pure matter. This conceptual framework is filled with original elements but not in isolation, as Whitehead spends meticulous effort in positioning his thought within the history of philosophy. In particular (Whitehead 1929b/1978, p. xi):

“These lectures are based upon a recurrence to that phase of philosophic thought which began with Descartes and ended with Hume. The philosophic scheme which they endeavour to explain is termed the ‘Philosophy of Organism’ [...]. In order to obtain a reasonably complete account of human experience considered in relation to the philosophical problems which naturally arise, the group of philosophers and scientists belonging to the seventeenth and eighteenth centuries has been considered, in particular Descartes, Newton, Locke, Hume, Kant.”

However, to the above list of referential figures, two Greek philosophers must be added, namely, Plato and Aristotle, to whom Whitehead evidently recognizes the fundamental ignition to all Western thought. Anecdotally, it has been said that Whitehead thought of the European philosophical tradition as a “series of footnotes to Plato.” As a matter of fact, Whitehead considers that two cosmologies have dominated European thought: Plato’s *Timaeus* and the seventeenth-century cosmology developed as a collaborative effort

between Galileo, Descartes, Newton, and Locke. Given his aim to produce his own framework, he believed “that perhaps the true solution consists in a fusion of the two previous schemes, with modifications demanded by self-consistency and the advance of knowledge” (Whitehead 1929b/1978, p. xiv).

In process philosophy there are three ultimate notions (Whitehead 1929b/1978, pp. 21–22): creativity, many, and one. The term “one” stands for the singularity of an entity. The term “many” conveys the notion of “disjunctive diversity,” and there is a multitude of beings in disjunctive diversity. “Creativity” is the universal of universals, by which the many, which are the universe disjunctively, become the one actual occasion, which is the universe conjunctively. In process philosophy, creativity is nothing less than the ultimate principle of metaphysics. Whitehead observes that it lies in the nature of things that the many enter into a complex unit, through creativity. Creativity is the principle of novelty, thanks to which an actual occasion is a novel entity diverse from any entity in the “many” which it unifies. A “creative advance” is the application of this ultimate principle of creativity to the conjunction of elements of the universe to originate novel situations, identified as “actual entities” or “actual objects.” But an actual entity is not a static object: it evolves through the “production of novel togetherness,” which is the ultimate notion embodied in the term “concrecence” (growing together). Thus an actual entity has a threefold character (Whitehead 1929b/1978, p. 87): “(i) it has the character ‘given’ by the past, the collection of its elements; (ii) it has the subjective character aimed at in its process of concrecence; (iii) it has the superjective character, which is the pragmatic value of its specific satisfaction qualifying the transcendent creativity.”

It appears then that process philosophy has many elements in common with pragmatism and with the original *panta rei* doctrine by Heraclitus. In fact, Whitehead states that: “The ancient doctrine that ‘no one crosses the same river twice’ is extended. No thinker thinks twice; and, to put the matter more generally, no subject experiences twice” (Whitehead 1929b/1978, p.

29). The application of creativity has the effect of producing vivifying novelty, in a process where the old meets the new, which is in a sense “selected” from the multiplicity of yet unexpressed potentiality (Whitehead 1929b/1978, p. 164). In Whitehead’s cosmology, creativity serves to place God and the World at extreme opposites. In each actuality two conrescent poles of realization can be identified: the “physical” and the “conceptual.” For God the conceptual is prior to the physical; for the World the physical poles are prior to the conceptual poles (Whitehead 1929b/1978, p. 384).

In process philosophy, realized temporal matter is transcended by “possibility.” The actual world, intended as a community of entities which are settled and actual, imposes conditions and limits to the potentiality for creativity beyond itself. This is a limitation to the general potentiality provided by eternal objects, which can however be overcome through novel realizations. Thus, relatively to any actual entity, there is a “given” world of settled actual entities and a “real” potentiality, which is the possibility for creativity beyond that state of the art. To Whitehead, this exemplifies the metaphysical principle that every “being” is a potential for a “becoming.”

In *Modes of Thought* (Whitehead 1938/1968), Whitehead elaborates on the intelligence of mankind basing his discussion on three fundamental notions: importance, expression, and understanding. The notion of importance is dominant in civilized thought, and it can be defined as “Interest, involving that intensity of individual feeling which leads to publicity of expression” (Whitehead 1938/1968, p. 8). Importance to Whitehead is that aspect of feeling whereby a perspective is imposed upon the universe of things. The two notions of importance and perspective are thus closely intertwined. The generic aim of the creative process is therefore the attainment of importance or a new perspective on the world. Expression is then necessary to diffuse throughout the environment something which will make a difference, due to its importance (Whitehead 1938/1968, p. 20). While importance is derived from the immanence of the

infinite into the finite, expression represents the immanence of the finite into the multitude on fellows beyond oneself. Taken together, importance and expression are witnesses to both the monistic aspect of the universe (through its overarching importance) and its pluralistic character (through the multitude of expressions). In Whitehead’s words (Whitehead 1938/1968, p. 20): “Importance passes to the world as one to the world as many; whereas, expression is the gift from the world as many to the world as one.”

Expression becomes the very reason of individual differences. While the laws of nature represent large average effects, whereby impersonality reigns, there is nothing average about expression. If average dominates, expression fades. Through human expression (Whitehead 1938/1968, p. 26):

nature seems to have burst through another of its boundaries. The conceptual entertainment of unrealized possibility becomes a major factor in human mentality. In this way, outrageous novelty is introduced, sometime beatified, sometime damned, and sometimes literally patented or protected by copyright. The definition of mankind is that in this genus of animals the central activity has been developed on the side of its relationship to novelty.

Therefore, according to Whitehead mankind is distinguished by its capacity for the introduction of novelty. This requires a conceptual power which can imagine and a practical power that can effect. In turn, this conceptual power is enormously increased by “language,” which Whitehead sees as the triumph of human ingenuity, surpassing even the complexity of modern technology. Language is the systematization of expression, and human civilization is an outgrowth of language: freedom of thought is itself an outgrowth of language. Whitehead raises language to a mystical role by stating that The souls of men are the gift of language to mankind. [...] *He gave them speech, and they became souls* (Whitehead 1938/1968, p. 41).

Finally, mankind can strive to interpret the universe in a quest for “understanding.” However, this goal is not reachable with our finite limitation, as “a complete understanding is a perfect grasp of the universe in its totality. We are finite beings,

and such a grasp is denied to us. [...] We can know anything in *some* of its perspectives. The totality of perspectives involves an infinitude beyond finite knowledge” (Whitehead 1938/1968, p. 42). This fact should not discourage us, as for Whitehead the essence of great experience is penetration into the unknown, the unexperienced.

Whitehead’s Legacy

Following Whitehead’s death, all of his papers were destroyed according to his explicit instructions. This element adds to the difficulty of assessing his influence and legacy, considering also the fact that during his lifetime he had many students but was not able to found a school of thought. Certainly, his determination in working on metaphysics was one of the main reasons why his thought was considered anachronistic at the time. However, Whitehead’s ideas in the third millennium are being revisited and revalued, and therefore his influence is presently undergoing a positive derivative (Mesle 2008).

Process theology, as derived from process philosophy, was perhaps the first item in the revival of Whiteheadian thought, thanks in particular to the activity of the Claremont School of Theology, as well as of the University of Chicago Divinity School. Charles Hartshorne, a prominent intellectual in the Divinity School in the years 1928–1955, considered that Whitehead had been a scientist at the level of Einstein and a philosopher at the level of Plato. A few tens of years later, the theologian John B. Cobb, Jr. embraced wholeheartedly the work of Whitehead and founded the journal of *Process Studies* in 1971 along with Lewis Ford, as well as the Center for Process Studies in 1973, in collaboration with David Griffin, in Claremont. A biannual International Whitehead Conference has been organized since 1981, the last edition of which (at the time of writing) was hosted by the University of Brasilia in August 2019. Recently, the most rapid trend of growing interest in

Whitehead’s work can be traced in China, in an effort to blend its traditional philosophies of Buddhism, Taoism, and Confucianism with the postmodern process philosophy. Multiple university centers for the study of Whitehead’s philosophy are being built in China.

However, it is important to underline that Whitehead’s influence today is far from being limited to the domain of religious-philosophical studies. For example, in the world of physics, the explanatory framework proposed by Rovelli (2017) is very much in line with a Whiteheadian interpretation, given that for Rovelli in the framework of quantum mechanics, there is no reality except in the relations between physical systems. The world of quantum mechanics is not a world of objects but a world of events. In the field of sociology, Halewood (2013) maintains that perhaps Whitehead was the most sociological of philosophers, due to his visions of things as “organisms” and thus “societies.” Finally, in the field of creativity and innovation studies, it can be stated that Whitehead’s approach to creativity as the fundamental construct of process philosophy, whereby potentiality is the eternal object and actual entities are dynamic instantiations, is in accordance to the dynamic definition of creativity (Corazza 2016): “creativity requires potential originality and effectiveness.” Also, the interconnectedness of all creativity episodes in the history of the world to form an active ensemble leads to the definition of the “dynamic universal creativity process” (Corazza 2019), conformant to Whitehead’s view of creativity as the ultimate principle of metaphysics. Certainly, Alfred North Whitehead and his process philosophy should be granted a central role in the study of the possible.

The Possible in the Life and Work of George Herbert Mead

Jack Martin

Department of Psychology, Simon Fraser University, Burnaby, BC, Canada

Abstract

George Herbert Mead (1863–1931) was an influential American pragmatist and social psychologist whose work assumed the inseparability and mutual reconstruction of human agency and the life world of persons. The exact manner of this relation is the subject of his social psychology. The harnessing of this relation with respect to human flourishing is the primary concern of his moral psychology. The former offers an explanation of how possibility emerges at the nexus of human agency and sociality. The latter offers a means of directing and adjudicating such possibility as it unfolds. In these ways, Mead is a useful guide to *the possible* in human conduct and life. His ideas have proved both enduring and provocative. His theories of the self, personal development, generalized others, sociality, emergence, agency, and social reconstruction continue to inspire and challenge many contemporary social theorists.

Keywords

George Herbert Mead · American pragmatism · Perspectival realism · Human agency · Sociality · Emergence in self and social development · Social Psychology · Moral psychology

Introduction

As his friend and colleague John Dewey recognized, George Herbert Mead was a theorist of *reconstruction*. For Dewey and Mead, one of the most basic problems of philosophy is the problem of reconstruction:

How are we to unite in a coherent way the presence of those relatively settled orders to which the name of all uniformities, laws, universals is given with the unremitting occurrence of individuality, novelty and the unpredictable? The idea of continuity, of remaking, of reconstruction was with Mr. Mead more than an idea in any abstract sense of the word; it was an immediate and lived feeling. (Dewey 1936, p. 329)

Mead “was continually engaged in the reconstructive development of his own ideas” (Dewey 1936, p. 330), which perhaps explains why he published so little during his lifetime. In his revised introduction to an edition of Mead’s essays on social psychology published in Strauss 1977, Anselm Strauss also applauds Mead’s “philosophical handling of the relations between permanence and change—that is the problem of continuity” (p. xii) as a major achievement. Strauss adds that it is an achievement that has yet to be fully and properly appreciated by most social scientists whose selection “from Mead’s writings was very restricted” (p. xii). In particular, Mead’s central “concept of perspectives . . . has not penetrated sociological thinking much nor has its implication for social change been understood” (p. xii). Because Mead’s conception of *perspectives* is so central to his handling of the problem of reconstruction (of reconciling continuity and change) and speaks so directly to what is possible in human affairs, its elaboration and explanation, within his theories of social and moral psychology, helps to clarify Mead’s primary contribution to what is possible in human life and conduct.

During his lifetime, Mead published about 60 articles, many of which were short reviews, notes, abstracts, reports, and commentaries somewhat incidental to his major ideas and subsequent contributions. All Mead’s books were based on his lectures and papers and were compiled, edited, and published by his friends, students, and others after Mead’s death in 1931. These include *The Philosophy of the Present* (1932); *Mind, Self, and Society* (1934); *Movements of Thought in the Nineteenth Century* (1936); *The Philosophy of the Act* (1938); *The Social Psychology of George Herbert Mead* (Stauss 1964); *George Herbert Mead: Selected Writings* (Reck 1964); *George Herbert Mead: Essays on his Social*

Philosophy (Petras 1968); *Play, School, and Society: George Herbert Mead* (Deegan 1999); and *Essays in Social Psychology: George Herbert Mead* (Deegan 2001).

Mead was born on February 27, 1863, in South Hadley, Massachusetts, to Reverend Hiram Mead and Elizabeth Storrs Mead, a teacher who served as president of Mount Holyoke Seminary and College. Mead himself studied at Oberlin College and pursued graduate studies in philosophy and psychology at Harvard and later in Germany. Although never receiving a doctorate, Mead returned from Germany to take a position at the University of Michigan at the invitation of John Dewey, whom he later followed to the University of Chicago where he remained until his death.

American pragmatism of the kind practiced by George Herbert Mead takes the position that “knowing the world is inseparable from agency within it. . . . [I]f a philosophical theory does not directly contribute to human progress then it is not worth much” (Legg and Hookway 2019). Mead’s entire oeuvre assumes the inseparability and mutual reconstruction of human agency and the life world of persons. The exact manner of this relation is the subject of his social psychology. The harnessing of this relation with respect to human flourishing is the primary concern of his moral psychology. The former offers an explanation of how possibility emerges at the nexus of human agency and sociality. The latter offers a means of directing and adjudicating such possibility as it unfolds. In these ways, Mead is a useful guide to *the possible* in human conduct and life.

Mead’s Social Psychology

The concept of *perspectives* is central to Mead’s philosophy of reconstruction. It pervades his theories of the self and personal development, the generalized other, sociality, emergence in social relations and via communication, intelligent social control and social reform, and science itself. It also underpins the promise of possibility that is ever present in Mead’s oeuvre. For Mead, “the mind in its reconstructive functioning is ‘a realm of continual emergence,’ and the emergence of

novel ideas in the mind is made possible by the social interplay of alternative roles and perspectives” (Cook 1993, p. 159).

The term *perspective* was not used by Mead until about 1920, after which time he developed what has been termed a philosophical position of *perspectival realism* (Martin 2005). Although Mead came to prefer the term *perspective*, he often used expressions such as “taking the role of the other,” “taking the attitude of the other,” and “taking the perspective of the other” interchangeably. For Mead, a perspective is an orientation to a situation that emerges through acting within that and similar situations. All perspectives arise out of human conduct, especially social exchange and interaction. Nonetheless, once entered into through situated conduct and interactivity, perspectives can take not only performative but also perceptual and conceptual forms. Hence, perspectives arise in situated interactivity but are not fixed to the particular contexts and times that mark their origins. Once experienced, perspectives can be used imaginatively.

The perspectival reality that matters to human beings (to persons) is not “out there,” independent of individuals and their actions, nor is it “in” individuals. It consists of the dynamic, ongoing interrelation of individuals acting within their life contexts. Our perspectival reality emerges out of “the relationship between the individual and the environment, and this relationship is that of conduct [i.e., action]” (Mead 1938, p. 218). For Mead, action with others in social contexts has both phylogenetic, historical, and ontogenetic, developmental primacy over isolated reflection of the kind privileged in much modern thought. During ontogenesis, it is through the child’s active and repetitive participation in routine action sequences with others that the child is able to take the perspectives of these others and learns to coordinate and comprehend different perspectives.

Mead (1934) often illustrated the emergence of perspectives within social interactivity with examples drawn from children’s games and routines such as hide-and-seek, tag, and various other forms of turn taking that involve repetitively moving between different positions, e.g., between

the positions of *hider* and *seeker*, *giver* and *receiver*, *speaker* and *listener*, and so forth. One is unable to be a hider without also being about to take the position, role, and perspective of a seeker. Similarly, later in life one cannot function as a buyer without being able to function as a seller. Through such interactivity, the child or the adult gradually is able to functionally coordinate two or more positions (e.g., that of hider and seeker or that of buyer and seller) by recalling, orienting to, and anticipating one position while acting in the other. Such functional simultaneity of related and organized positions and perspectives is what Mead means by sociality. The child or adult becomes “an object to himself by taking the attitudes [perspectives] of others toward himself within an organized setting of social relationships” (Mead 1934, p. 225).

It is by taking, exchanging, and coordinating different positions, and the perspectives associated with them, during social interactivity that we develop a sense and action-based understanding of ourselves as subjects and objects. In addition to taking the perspectives of particular others with whom we interact, such perspective taking, exchange, and coordination also enable us to take the perspective of various “generalized others,” i.e., of social groups, communities, or societies as a whole. For example, to take on the position and perspective of a second base player in baseball requires entering into the positions and perspectives of the other players. To function as a family member, one must view oneself from the perspectives of other family members and the entire family system.

When a child or adult is able to act and orient to herself as others do, she behaves as a *me*, as a member of a social group. The “me” represents “the value of the group, that sort of experience which the group makes possible. Its values are the values that belong to society” and which give a “structure to things” without which “the life of the self would become impossible” (Mead 1934, p. 214). With the emergence of a “me,” the child can both connect to and distinguish herself from others. “One attains self-consciousness only as he takes, or finds himself situated to take, the attitude [perspective] of the other” (Mead 1934, p. 194).

However, through social interactivity the child also responds in her conduct to the perspectives of others (both particular and generalized others) as an “I,” the “values of which are found in the immediate attitude [perspective] of the artist, the inventor, the scientist in his discovery, in general in the action of the ‘I’ which cannot be calculated and which involves a reconstruction of the society, and so of the ‘me’ which belongs to that society” (p. 214).

For Mead, the “I” and the “me” are not meta-physical distinctions and certainly not metaphysical entities. They are functional distinctions concerning modes of personal being within social conduct. In reflecting one’s social experience and the perspectives of others, the “me” takes itself as an object formed by life experience drawn from the immediate and distant past, understood as the sequence of “presences” that a person has lived through. In reflecting one’s barely glimpsed immediate perspectives, the “I” is an agentive subject moving into an uncertain future as a creator of experience and action, experiences and actions that once achieved pass immediately into the “me,” while the ever active, agentive “I” forges ahead with only the merest glimpse of itself in passing. The distinction between and the functioning of the “I” and the “me” are among the most debated and criticized aspects of Mead’s perspectival realism. Yet, the functional distinction between these two modes of personal being is closely linked to Mead’s ideas concerning the continuous, mutual emergence of persons and their life world. The entry for “► [Position Exchange Theory](#)” in this handbook offers further discussion and clarification of the emergence of self and other understanding and personal agency from a neo-Meadian perspective.

Once developmentally emergent, all persons, children, and adults are locked into a process of continuous perspectival reconstruction that opens to a world of constrained possibility. In later childhood and adulthood, interaction and communication with others are increasingly driven by what Mead calls “significant symbols.” The use of these linguistic tools marks an important transition from communication through gestures and positions to conversation through a

shared language. This transition dramatically accelerates and multiplies the perspectives and possibilities that can be acquired and exchanged with others by adding a symbolic order to the physical interactivity of the infant and younger child. Significant symbols “call out” in the person who gestures or speaks a functionally similar response to that they demand or intend from those to whom they are directed. For example, if a preoccupied friend fails to respond immediately to my request to share a section of the newspaper she’s reading, I might help myself to a section of that same newspaper. Using a shared language assists speakers and listeners (or writers and readers) to immediately grasp nuances and variations in perspectives communicated that would mostly be unavailable without the significant symbols of language. As our individual lives and linguistic, communicative competence progress, we become capable of much more abstracted, reflective, purposeful, and higher-level forms of perspective taking, exchange, coordination, and reconstruction that draw from both direct and vicarious experience. Whenever we take the perspective of another or a group of others, we reconstruct ourselves and enter into the simultaneous reconstruction of others and the social groups and structures within which we interact.

What allows Mead’s perspectival realism to function as both an opening for possibility and a constraint on human conduct is the organization of perspectives within the biophysical and socio-cultural world. Through their interactivity and experience in this world, it is possible for individuals, collectively and individually, to subject their perspectives to appropriate forms of test. The organization of human conduct within social contexts and structures is constantly changing but nonetheless typically provides sufficient stability for individual and collective problem-solving. In other words, it balances continuity and change, which is the basic requirement of the ongoing process of reconstruction that Mead and Dewey understood as central to human experience and life.

At the beginning of interactions with others in problematic circumstances, all that might unite the different perspectives of potential problem-

solvers may be a shared desire to remove a difficulty that confronts all of them. However, over time, and with accumulated interactions and exchanges concerning a variety of possible strategies and actions, problem-solvers are likely to gain a greater understanding and appreciation of the feasible possibilities potentially available to them. What ultimately organizes these various perspectives and possibilities is the extent to which they achieve collective support among those intent on resolving the problem or difficulty at hand. Typically, perspectives and their associated possibilities are organized in terms of their utility and viability within the problem situation and related contexts, immediately and in the foreseeable future. The discussion and organization of a viable plan of action “leads to creative reconstruction. In so far as the world is passing into a future, there is an opportunity for that which is not objective to become objective” (Mead 1938, p. 613). Such problem-solving both requires and enhances the sociality of all those involved because it promotes each participant’s consideration of a diversity of perspectives through which they are able to prepare themselves for emergent events that inevitably will have novel, unexpected consequences. For Mead, the immediate moment of action brings together a concern of the present with both recollections of relevant past activity and anticipations of a future in which the concern or problem to which the action of the present is directed is resolved or somehow made manageable.

At a personal level for each problem-solver, the “me” to which the “I” is reacting is determined within a knowable past. On the other hand, the “I” of the moment must act in circumstances that are not entirely predictable from the past and which are in part explicable in terms of an imagined future state in which the concern or problem of the moment somehow has been ameliorated. In these instances, the person occupies two distinct temporal perspectives, one in which the “me” as object is determined and another in which the “I” as agent is not determined. Of course, once the action in question takes place, it, together with whatever perspectives or perspectival transformations it might occasion, becomes part of a “new”

knowable past, which can be used to anticipate a newly emergent concern of the moment and a “new” future. And so it goes.

Mead’s Moral Psychology

After Mead followed Dewey to the University of Chicago, he developed a secular, “functionalist moral psychology that construed moral problems, moral consciousness, and moral decision-making as functional phases of a reconstructive process taking place within human conduct” (Cook 1993, p. 116). This moral psychology was later reworked after he had developed the social psychology just described. Mead consistently believed that moral progress occurs through reconstruction in attempts to resolve moral problems.

Moral problems stem from competing perspectives in the social organization of the self, which often takes the form of an internalized conversation, with a covert articulation of each perspective calling out a response in the other perspectives.

Assuming as I do the essentially social character of the ethical end, we find in moral reflection a conflict in which certain values find a spokesman in the old self or a dominant part of the old self, while other values answering to other tendencies and impulses arise in opposition and find other spokesmen to present their cases. . . . The result is that we state the other conflicting ends in subjective terms of other selves and the moral problem seems to take the form of the sacrifice either of the self or of the others. Where, however, the problem is objectively considered, although the conflict is a social one, it should not resolve itself into a struggle between selves, but into such a reconstruction of the situation that different and enlarged and more adequate personalities may emerge. Attention should be centered on the objective social field. . . . In the reflective analysis, the old self should enter upon the same terms with the selves whose roles are assumed, and the test of the reconstruction is found in the fact that all the personal interests are adequately recognized in a new social situation. The new self that answers to this new situation can appear in consciousness only after this new situation has been realized and accepted. . . . Solution is reached by the construction of a new world harmonizing the conflicting interests which enter the new self. . . . The growth of the self arises out of a partial disintegration—the appearance of the different

interests in the forum of reflection, the reconstruction of the social world, and the consequent appearance of the new self that answers to the new object. (Mead, in Reck 1964, pp. 148–149)

To overcome a dominant self-perspective requires an approach to moral problems that attempts to do justice to the various competing personal and social interests present within the problem situation, allowing them to enter into a dialogue as equally plausible alternatives. Instead of clinging to old selves and their attendant perspectives, such a dialogue aims at a reconstruction of the situation that allows a new “enlarged and more adequate” (Mead in Reck, p. 148) self and perspective to emerge. Thus, what appear as intractable moral problems only can yield to a process and logic of moral reconstruction in the face of problems or conflicts. The successful moral reconciliation works by combining and tailoring conflicting values and perspectives within a more inclusive self and emerging social cohort.

Mead applied his multiperspectival, integrative approach to moral problems to national and international conflicts between nations in an essay entitled “The Psychological Bases of Internationalism” (Mead 1915), a series of newspaper essays he published in the *Chicago Herald* during 1917, and in his later essay “National-Mindedness and International-Mindedness” (Mead 1929). In these works, he treats the genesis of national self-consciousness as analogous in important functional respects to the genesis of individual self-consciousness, arguing that nations, like individuals, only can see themselves through the eyes of others and come to understand themselves more fully only by participating in a larger social process and order. In the aftermath of World War I, Mead pleaded that both nations and their citizens must strive to move toward wider and more productive and inclusive forms of international consciousness. In his essay “Philanthropy from the Point of View of Ethics,” Mead states that it is the morally reflective person’s “feel for a social structure which is implicit in what is present” that provides “a sense of obligation which transcends any claim that his actual social order fastens upon him” (reprinted in Reck 1964, p. 404). In the face of a moral problem or conflict, it is this sense of obligation that searches actively for a hypothetically alternative

order within which the problem or conflict can be reinterpreted and resolved. “It is an ideal world that lays the claim upon him, but it is an ideal world which grows out of this world and its undeniable implications” (in Reck 1964, p. 404).

Mead’s moral psychology calls on persons to recognize their common status as socioculturally constituted beings whose customs, habits, and values appear as individual goods that they share with others within their community and to recognize that the same is true for diverse individuals dwelling and living in other communities. In so doing, it becomes clear that, given this inevitable state of affairs, the only way forward is somehow to transcend the local orders of the various communities in conflict. Mead’s proposal is to encourage such transcendence by imagining hypothetical social orders within which individuals and nations in conflict can place themselves outside their differing community orders as they currently exist and construct possibilities for functioning within a new and shared social order that encourages common actions to resolve conflict, actions based on commonly recognized conditions of conduct and common ends.

Like his social psychology, Mead’s moral psychology has attracted numerous critics. For example, Hans Joas has accused Mead of insufficient insight into his own nation and excusing its practices of power, thereby inadvertently falling “into the sins of nationalism” (Joas 1997, p. 25). Mead understood the First World War as a “contest between democracy and autocracy” (Cook 1993, p. 123), and his subsequent internationalism arguably retained a demonstrably American perspective. Indeed pragmatism itself is tightly entwined within various strands of American life and values. Others have recognized what they consider to be unfortunate gaps and inadequacies in both Mead’s social and moral psychologies to which they have proposed modifications and extensions (e.g., Gillespie 2005; Martin 2005).

Conclusion

Whatever the strengths and weaknesses of his social and moral psychologies, Mead undoubtedly must be considered one of social science’s

most significant thinkers about possibility, specifically what is potentially possible with respect to humans' command and direction of their personal and collective conduct with respect to the furtherance of human beneficence. As mentioned earlier, Dewey recognized that Mead was driven by an urgency to understand how human continuity could survive human ingenuity. As Dewey also recognized, Mead's own oeuvre is testimony to and illustration of the constant process of reconstruction Mead thought essential to human flourishing in a world of diverse and often competing perspectives.

In a recent commentary, Glăveanu (2019) describes Mead's lasting contribution to our understanding of creativity as steeped in human sociality.

We are capable of creativity not because we are separate from others and distinct from them; on the contrary we gain our individuality from being able to engage with the perspective of others and creatively transform it and ourselves in this process. The emergent self is, in this sense, not individual *despite* being social but, rather, *because* of it. (Glăveanu 2019, pp. 443–444)

Mead's perspectival realism places creativity and possibility within an always present human sociality constituted by our everyday positioning within our own perspectives and those of others with whom we interact. Feats and accomplishments that we recognize and deem creative do not differ in kind from the quotidian adjustments we make to our acting and thinking as a consequence of interacting with others directly and indirectly. Sociality as the functionally simultaneous immersion in multiple perspectives is endemic and inescapable in the lives of persons in interaction with others. Our social lives with others are constant resources of possibility that reside in the fusion and integration of perspectives in ways that solve problems and yield advances, both minor and major. Those we consider geniuses:

make the wider society a noticeably different society ... simply by carrying to the *n*th power this change in the community ... [T]hey have enlarged and enriched the community. ... They represent, in their personal relationships, a new order, and then become representative of the community as it might exist if it were fully developed along the lines that they had started. (Mead 1934, pp. 216–217)

Reconstruction involves the building of something new from what is past, current, and evolving. Perspectives fuel reconstruction as they ebb and flow, come together, and separate, charting a course for the future framed, yet eclipsed by an unfolding present moving into an only semi-predictable future. The person in her reconstructive functioning is caught up in a realm of continual emergence. The emergence of novelty in persons and their social contexts and practices is a consequence of the interplay of individual and collective perspectives. It is this world of perspectival possibility that Mead explored and theorized in his writings in social and moral psychology, which constitute his unique contributions to American philosophical pragmatism.

Yet, against the positive and progressive examples and images in his writings about possibility and change, human interactivity concerning different perspectives also includes regressive and destructive possibilities that might emerge, and have emerged, throughout our collective history of interactive and attempted perspectival sociality. There is nothing in Mead's social psychology that necessarily guards against such more dire possibilities. Whether or not his moral psychology, with its themes and assumptions of cooperative accommodation and open-mindedness, has sufficient resources to provide such safe guards is an open question, but one that probably cannot be left to optimism alone.

Nonetheless, Mead's writings repay attention. In Dewey's memorial tribute to Mead, he emphasized the reconstructive power of Mead's ideas, saying that they "worked a revolution in my own thinking, though I was slow in grasping anything like their full implications" (Dewey 1931, p. 313). Mead's oeuvre continues to invite re-examination and elaboration for the insights it contains concerning what is possible through human agency and sociality.

Summary

George Herbert Mead's social and moral psychologies constitute an innovative and important body of ideas concerning possibility in human social life. His attempts to explain and reconcile human

continuity with ongoing change in both selves and societies offer much to both social theorists and reformers. By carefully considering and interpreting interactions with others as involving a continual exchange and interplay of positions and perspectives, Mead developed original and progressive social and moral psychologies that continue to demand the attention of scholars in the social sciences and beyond.

The Possible in the Life and Work of Gregory Bateson

Wolfram Lutterer

Central and University Library, Lucerne,
Switzerland

Abstract

The Anglo-American anthropologist Gregory Bateson is one of the core thinkers of a systemic worldview, inspired by cybernetics. His thoughts also include ecological issues. Though he did not strictly argue about the possible, his work delivers several hints and aspects into a broader understanding. This entry presents 10 aspects of Bateson's work

in relation to the possible with focus on communication, on behavior, and on philosophical issues. A systemic approach inspired by Bateson also includes observations about the “not possible” and the “not desirable.”

Scientific and Biographical Issues

Bateson's live and work are already subject of a comprehensive biography by David Lipset (Lipset 1982). There are also two major studies by Peter Harries-Jones, one focusing on his later works (Harries-Jones 1995), and the other one taking broader view, beginning with his early writings (Harries-Jones 2016). The maybe most authoritative study on Bateson's theory of mind and on ecological issues in his work is given by Noel G. Charlton (Charlton 2008). Finally, there is an analysis of his complete works by Wolfram Lutterer (Lutterer 2000). Therefore, this section will be quite short.

Bateson was kind of a “scout” (Toulmin 1982; 201), a pioneer or a wanderer in and between different scientific fields. Beginning as an anthropologist in the 1930s, he started with explorations on a tribe of former headhunters in New Guinea (Bateson 1936), followed by a photographic study of *Balinese Character* with Margaret Mead in the early 1940s (Bateson and Mead 1942). In the late 1940s, he was part of the famous *Cybernetics Group* (Heims 1991) (see Cybernetics). This resulted in the development of a highly influential communication theory that he co-authored with the psychiatrist Jürgen Ruesch in the early 1950s (Ruesch and Bateson 1951), and which resulted eventually in the shaping of his own scientific approach. The focus on research on communication was also core of his following research, being this on play and fantasy, on the communication patterns of schizophrenics and thereby in his famous *double-bind-theory*, all in the 1950s.

A further change of his scientific scope brought him even into the exploration of the

communication of octopuses, and also of dolphins in the 1960s (cf. Bateson 2000). In 1962, Bateson finished his research in Palo Alto and wandered also professionally into dolphin research, first in the Virgin Islands and later in Hawaii.

The 1960s were also a time of a growing understanding of ecological issues. One of the most influential writings of that time was Rachel Carson's *Silent Spring* (Carson 1962), perhaps a kind of a wake-up call also for Bateson himself. Anyway, in a short and dense essay on the *Roots of Ecological Crisis*, he mentions Carson's book as the only one scientific source (Bateson 2000, p. 496). Thus, Bateson's most important life topic was borne: from cybernetics to communication theory, then to ecology, to systemics, to a new theory of mind, in building a new approach to ecology and also to evolution theory, and developing a systemic view up to a reflection to the meaning of the sacred. Topics such as these cover about a third of the essays collected in *Steps to an Ecology of Mind*, published in 1972 (Bateson 2000). In the same year, Bateson moved to Santa Cruz, California, to teach at the university, culminating in his appointment as one of the Regents of the University of California in 1976.

This scientifically fruitful period included another monograph, a first synthesis of his systemic approach, entitled *Mind and Nature* (Bateson 1979). Bateson died one year later while working on another even more far-reaching book, published some years later by his daughter Mary Catherine Bateson: *Angels Fear: Towards an Epistemology of the Sacred* (Bateson and Bateson 1987). In addition to this, Rodney E. Donaldson published a second collection of Bateson essays, titled *A Sacred Unity* (Bateson 1991).

Research on Bateson

A complete bibliographic survey of research inspired by Bateson (hereafter also abbreviated as “GB”) or even of the research on his works does not yet exist. Therefore, we can only give some clues.

Beginning in the late 1970s, there were published three main somehow “classic”

collections of essays on GB (Brockman 1977; Wilder-Mott and Weakland 1981; Rieber 1989). These all provide a fairly intensive overview of how his work was understood at that time. But surely it is more inspiring to take a look on some more recent publications. The already mentioned Noel G. Charlton declares to give “an accessible introduction to the work” of GB (Charlton 2008, p. 1), but in fact he provides more and less in one, as he puts a strong focus on GB’s late works. In context of the ecological crisis, Charlton discusses GB’s theories of mind, of beauty, and especially of the sacred. Building on this, Yoni van den Eede delivers a study of a possible “Batesonian Philosophy of Technology” (Eede 2019), in which he observes a subtle disappearance of technology, but just this also embedded in GB’s theory of mind. In an also philosophical approach, Morris Berman draws a loop from the Age of Enlightenment to a possible “reenchantment of the world” (Berman 1981).

GB’s early works were issue of a study by Arthur Chaney (Chaney 2017) and also by Peter Harries-Jones (Harries-Jones 2016). Both draw also outlines into his later writings. More focused on GB’s theory of mind and nature, Roger Duncan explores a “Nature in Mind,” in following GB’s “unfinished business” consisting in a new connection of mind with nature (Duncan 2018, p. 2). GB is also viewed as a “precursor to biosemantics” by Jesper Hoffmeyer and others (Hoffmeyer 2008). A rereading, and an extension of GB’s learning theory in a synthesis with Jean Piaget, is done by Wolfram Lutterer (Lutterer 2011).

Although not the classical kind of research, a dense approach to GB is provided by his daughter Nora Bateson with her partially autobiographic film, which is surely the most direct and rapid access to a Batesonian way of thinking (Bateson 2011).

Bateson and the Possible

Bateson’s work contains multiple reflections related to “the possible.” This section highlights some of GB’s insights on the way to a more comprehensive approach to the possible,

following some chronological paths throughout his writings in 10 steps.

First Step: Strict and Loose Thinking

As early as 1941, GB muses about conditions for the scientific progress itself. How does science proceed and how could this process possibly be accelerated? He observes two processes that have to work together. First, there is “loose thinking,” meaning the development of new ideas and this often by pure speculations, and therefore “building of an edifice,” but still on rather rough foundations. The second process is the “correction of the foundations,” which can happen years or decades later. These two he describes as a necessary combination of “strict and loose thinking” (Bateson 2000, p. 86). Thus, he observes a dual nature of the scientific progress. One needs both, the “loose” thinking, perhaps even purely speculative thinking, but also the “strict” thinking that embeds new thoughts into the scientific process, developing and altering science as such. So, this is the first of my “steps to the possible” in regard to GB. You have to put up with creativity and maybe also sometimes seemingly crazy ideas to come up with something new. Bateson himself will rephrase this in his use of Charles Peirce’s idea of “abduction,” later on.

Second Step: Meta-communication

In 1951, GB publishes with Jurgen Ruesch *Communication: The Social Matrix of Psychiatry*, a book that has influenced many, from Paul Watzlawick (Watzlawick et al. 1967), to John Grinder and Richard Bandler (Bandler and Grinder 1975), up to systems theorist Niklas Luhmann (Luhmann 1995).

Bateson and Ruesch offer therein a distinction between “communication” and “meta-communication.” Communication is never “pure” in the sense of that time information theory (see Shannon 1948), there is no pure sending and receiving of data or of information. Any understanding of the exchange of information between a sender and its receiver is dependent of several conditions, in particular “all exchanged cues and propositions about (a) codification and (b) relationship between the communicators”

(Ruesch and Bateson 1951, p. 209). These processes of codification and of relationship were defined as *metacommunication*: The understanding of the meaning of given words is dependent from the metacommunication, for example, in talking just ironically about something. Bateson further develops this into his ideas about context and also about relationship. And he emphasizes: By metacommunication, we discuss also the “patterns of our relationship” *prior* to the possible content of the communication (Bateson 2000, p. 372).

Third Step: Context

The concept of “context” is crucial in this whole discussion. It is developed in a short essay containing a speculation about play and meta-communication, entitled *A theory of play and fantasy*, a lecture held in 1954. It seems somehow fitting that the notion of context – or alternatively: *frame* – is developed in the context of something else. GB’s ideas about context were echoed by Erving Goffman (cf. Goffman 1974) and by Steve de Shazer (Shazer 1985).

GB observes the play of animals, especially of young monkeys and also of fish otters. The point here is that many animals are able to distinguish between a real threat and one given only in play. Three types of contexts or frames are discussed hereby: messages that are “mood-signs,” “messages which simulate simulate mood-signs,” and also messages which help the receiver to distinguish between both (Bateson 2000, p. 189). Therefore, also animals are able to meta-communicate. A playful bite is not a real bite and is understood as such, and in our human world: Watching *Hamlet* on the stage shouldn’t bring the audience to call the police because of the given information about death and possible suicide (Op. cit., p. 290).

The discussion about frames brings GB to the phenomenon of paradox: The “playful nip” doesn’t only denote a bite itself, the “bite itself is fictional” (Op. cit., p. 182). In this discussion about contexts and frames, the possible emerges in several ways. A frame provides a necessary piece of information about the interaction it frames. Without context, there is no meaning.

However, a frame can also be altered, a realization that is fruitful especially in psychotherapy. Bateson concludes his discussion of context – and of frame – with a remark what would be without our ability to metacommunicate: “Life would then be an endless interchange of stylized messages, a game with rigid rules, unrelieved by change and humor” (Op. cit., p. 193).

Therefore, a discussion about the possible is also a discussion about context. Bateson’s next step is to discuss the communication of schizophrenics by *double bind theory* (Bateson 2000, p. 201; see also Sluzki and Ransom 1976). But even more at the question of the possible is his learning theory.

Fourth Step: Learning to Learn

Bateson’s learning theory can be seen as another aspect of context sensitivity. All in all, GB distinguishes five levels of learning (Learning 0 to Learning IV, see Bateson 2000, p. 279), but on this point only the difference between *Learning I* and *Learning II* will be discussed. Appropriately, the development of this theory had also its stages in covering a long period, from 1942 to 1971.

Basically, Learning I is comparable to our understanding of everyday learning, and therefore, for example, how you learn to drive a car, in learning some new vocabulary, or in learning some news about the world. In fact, the classical psychological learning experiments cover usually just Learning I: You know, or you do – or sometimes even do not – something you didn’t before. As GB mentions, “learning I is change in specificity in response by correction of errors within a set of alternatives” (Op. cit., p. 293). But learning like this stands inevitably in a context, or more precisely: it is a double-sided process where repeated learning situations influence the expectation how learning should be. But also, the other way around: our expectations themselves frame, what and how we will learn. This is in quite short Learning II. For GB, our worldview and even our character are a result of (or alternatively correlate with) Learning II.

GB’s learning theory is at the background of Pierre Bourdieu’s concept of *habitus* (Bourdieu 1984). In regard to the possible, GB’s message at

this point would be: You are not just “dependent” or “narcissistic” by yourself, these are also results of repeated learning experiences, and this all his just behavior in context to other behavior, therefore not simply “inside” yourself. Therefore, Learning II is double-sided in itself: in case of habitus, it tends to blockade new experiences, but it also stands for the fact that our deep truths about reality are only constructions and thus changeable. So, the possible can be made impossible just by our expectations – and vice versa.

Fifth Step: Cybernetic Explanation – The Impossible

If one were ever trying to construct a complete theory of the possible, it would necessarily also include its opposite, the *impossible*. At this point, it might be helpful to think about the “Cybernetic Explanation” as GB sees it (Bateson 2000, p. 495). The main difference between the common causal explanation and the cybernetic explanation is that the former is “usually positive” while the latter is *negative*. The question shifts from “how has this happened” to “what else could have been possible and what has hindered it from to be happened” (Op. cit., p. 405). Therefore, cybernetic explanation is looking for restraints. The idea is not be satisfied with the too easy and always reductionist approach that causal theories suggest that just one event is the reason for another and so on.

Cybernetic explanation as GB understands it seems therefore a standard wherever multi-causality or complexity are included even if not mentioned as such. You take a look at the alternatives and why they didn’t occur. Even a seemingly simple event like a car accident is seldom so simple to explain that one has just hit the other, and that’s it. A satisfying description of an event just like this wouldn’t be complete, and on behalf of science – as also juristically – is therefore basically flawed.

Sixth Step: Information as a Difference

The possible is not always the desirable. This could be a consequence of a systemic view on information. The conventional understanding of information desires especially from the so-called

information theory of Claude Shannon. The idea thereby is that a sender sends, and the receiver receives information, and the only question between both of them is if data channel is sufficient for the transmitted signals (Shannon 1948). But this covers only a *mathematical* sense of signal transmitting. But do you really use mathematics to understand the meaning of information?

Bateson defines information as “a difference which makes a difference” (Bateson 2000, p. 459), and he bases his argumentation on Immanuel Kant’s *thing-in-itself*. The “piece of chalk” you see “can never enter into communication or mental process” (Op.cit., p. 459). There are only transformations of differences: Of differences between the chalk and its environment and of the perceived differences in the structure of the chalk. So the neural “signal” or “impulse” is better to be defined as “news of a difference.” And this is it what eventually makes another difference in our mind. Is it relevant to see the piece of chalk? Which meaning has it? What is the meaning of that funny lines that somebody draws with the chalk on a blackboard? Seeing information as a difference which makes a difference shows that it is the so-called receiver who decides what and how some given signals are understood as information or as something else, an epistemological fact which was also stressed by Humberto Maturana (Maturana and Varela 1987) and by Heinz von Foerster (Foerster 1980). Therefore, the information somebody likes to share can be possibly received as something else.

Seventh Step: Ecology of Mind

Considering consequences of GB’s thinking, one may come to a similar result like him, by also setting *mind* in a context. His famous example for this is a blind man with a stick: “Where do I start?” Where are the boundaries of the self? At the skin? At the end of the stick? But all these are “nonsense questions” for GB: in his view, *mind* spans the whole system of the information processing. Therefore, “The elementary cybernetic system with its messages in circuit is [...] the simplest unit of mind” (Bateson 2000, p. 465).

So while Sigmund Freud’s psychology “expanded the concept of mind inwards,” GB

expands it outwards (Op. cit., p. 467). GB develops these ideas in opposition to a fundamental flaw in our epistemology as he sees it. It is our “purposive consciousness” which fails in perceiving feedback loops and the “systemic nature” of the individual, of his culture, and also of the “ecological system around him.” This failure consists in cutting out only “sequences” of the systemic structure (Op. cit., p. 440), in the obsession to create cause-effect relations in the shortest possible way. These ideas were developed in two lectures given in 1968 and in 1970, titled *Conscious Purpose versus Nature and Form, Substance and Difference*. These are two of the densest and maybe most fundamental single works of GB. An even more extensive discussion of his theory of mind GB delivers in *Mind and Nature*, including a definition of mind with six criteria (Bateson 1979, p. 101).

But as it seems, GB’s ideas about mind, about epistemology, and also about ontology have often “been misunderstood and misrepresented,” as Noel Charlton points out. But they “contribute vital dimensions to the possibility of our human reintegration into the living world” (Charlton 2008, p. 66). So there still seems to be something almost revolutionary about these ideas, moving away from the old school scientific approach of separating and cataloging phenomena into the systemic way of following relations and interactions in a multiple way. Nevertheless, there seems to be “something elusive about the Batesonian framework” (Eede 2019, p. 13). Small wonder: setting mind in a context and thereby “out of the brain” remains something different.

All in all, GB’s theory of mind represents a far-reaching horizon of possibilities, at which at this place only can be hinted at. Based on this theory of mind, he develops an alternative approach to ecology, and also of our self and of our connectedness with our social and natural environment. Unfortunately, misinterpretations are all too easy: But there is nothing supernatural in GB’s theory of mind, only circular causality, and systemic understanding: “It shows us an interconnected world with humans in membership but not separate, superior, independent, or immune from wider systemic effects” (Charlton 2008, p. 163).

Eighth Step: Double Description

Another step: double description. With a list of nine examples, GB illustrates the idea that “*combining* information from two or more sources” brings a bonus: “two descriptions are better than one” (Bateson 1979, p. 77), also called *double description* (p. 227). The most elemental of his examples is the term of *difference*. You need “at least two somethings to create a difference” (p. 78). Other examples are the binocular vision – seeing with two eyes enables spatial vision – or the discovery of the planet Pluto – irregularities in the orbit of Neptune resulted in the necessary existence of another planet.

GB’s idea of double description can also be applied to the scientific approach itself. Then you observe some behavior not only with the eyes of a psychologist but also through those of a sociologist, a biologist, an economist, a philosopher, or whoever. The point here is not arbitrariness, but a more complete view of a case that breaks away from a simple-minded reductionism. So, the possible arises in an enrichment of the scientific approach to a given case.

Ninth Step: Abduction

How do we draw conclusions? The formal logic proposes for this the so-called *modus barbara* which runs as such: men die; Socrates is a man; Socrates will die. But GB observes that our mental process often runs in a completely different way. His example is “Grass dies. Men die. Men are grass,” also ironically named as “syllogism in grass” (Bateson 1991, p. 240). GB uses here a distinction developed by Charles S. Peirce, called *abduction* (see also abduction). Peirce distinguishes three kinds of reasoning: deduction (e.g., *modus barbara*), induction (e.g. I observe only white swans, therefore all swans have to be white), and abduction (Peirce 1958, p. 5.189).

Following Peirce, GB emphasizes that the *barbara syllogism* is dependent from the “invention of language” whereby the grass syllogism precedes. An abduction already happens when we observe some rules and apply them. GB concludes “all thought would be totally impossible in a universe in which abduction was not expectable” (Bateson 1979, p. 157). An example for

this: Every time you start to draw cash from a cash machine, you simply expect that this machine is similar just like the last one, and that it just doesn't something else.

With a loop back to GB's early work on strict and loose thinking, abductions often happen by the so-called loose thinking. But we necessarily trust in the similarity or even the identity of our environment of yesterday with today. Therefore, abduction has two aspects in relation to the possible: On the one side, abductions make the possible just possible. But on the other side, it can also hinder new possibilities, especially if we insist that our world of today would be just the same as of yesterday. This can be observed, for example, in the denial of the arisen ecological crisis and is also a result of a Learning II process, as GB sees it.

Tenth Step: The Sacred and Noncommunication

Again: the possible is not always the desirable. This is, in short, a result from GB's ideas about an "Epistemology of the Sacred," so the subtitle of his unfinished last book *Angels Fear*, some years later edited, enriched, and completed by his daughter Mary Catherine Bateson (Bateson and Bateson 1987).

GB observes therein phenomena which demonstrate that "*not communicating* something under some circumstances" is sometimes important (Op. cit., p. 79). One of the given examples is a story inside a story. GB delivered a speech at the Californian Governor's Prayer Breakfast in 1975. He told a story about Native Americans who were not willing to be photographed in order to save their religious rituals involving psychedelic substances. But taking pictures would have brought their "very personal matter of prayer" (Op. cit., p. 72) to the public, which was just impossible for them. So, the Native Americans declined and risked the acceptance of their rites as religious. GB's speech itself resulted in the interdiction of photographing of the participants of the event, since this too would be "a sacred and not a secular occasion" (Op. cit., p. 75). GB comments this that sometimes "communication is undesirable, not because of fear, but because communication would somehow alter the nature of ideas"

(Op. cit., p. 80). This phenomenon he also describes as something which could be called *sacred*.

These late thoughts of GB also supplement and complement GB's earlier theory of the *double bind* (cf. Bateson 2000, p. 201). In the observation of the communication of schizophrenic people, there were observed contradicting messages in communication and metacommunication, consisting also in a interdiction to talk about the suffered contradictions. But here, again in regarding some core processes of the human communication and relationships, it is just the other way round. Not talking is sometimes better, because talking about it would alter the situation in a not desired way.

Summary

This entry has approached ideas of the anthropologist Gregory Bateson related to the possible. Following the title of one of his major publications, *Steps to an Ecology of Mind*, this was presented in 10 steps. These steps also reveal a *systemic approach* to the possible. So, all in all, they constitute an eleventh step since GB is one of the most influential thinkers of a systemic worldview. In this understanding, the discussion about possible was enhanced and enriched by the "not possible," the "also possible," and even the "desirable."

The Possible in the Life and Work of Henri Bergson

Steven D. Brown¹ and Craig Lundy²

¹Nottingham Trent University, Nottingham, UK

²London Metropolitan University, London, UK

Abstract

Henri Bergson (1859–1941) contributed major philosophical works on time, consciousness, evolution, and morality. His thinking remains central to debates on fundamental issues within philosophy and social science, particular around “process ontology.” Bergson’s work was of enormous influence to early-twentieth-century social science, and has seen a resurgence in the twenty-first century. This is in part due to the reception of Gilles Deleuze’s work, which engaged extensively with Bergson. In this entry, we focus on Bergson’s treatment of the relationship between “the possible” and “the real.” Bergson inverts the Platonic organization of these terms, where the real is constituted by the selection of ideal forms of possible. Bergson argues that this makes it impossible to understand how “unforseeable novelty” might emerge in the world. The possible is instead a “mirage” retrospectively posited as prior to

the real. This treatment is part of a broader project of overcoming metaphysical mistakes which consist in seeing one philosophical term as adding fullness and positivity to another. In its place, Bergson offers an account of life as dynamic, autopoietic emergence. In the final part of the entry we describe how an engagement with Bergson can afford social science approaches to memory, imagination, and lived experience as emergent patternings of life responding to life.

Virtual · Duration · Lived Experience · Vitalism · Memory

Introduction

Henri Bergson (1859–1941) was arguably the preeminent French philosopher of the early twentieth century. Beginning with *Time and Free Will* (1889 [2001]), Bergson worked extensively on a philosophical treatment of time that sought to decouple it from a confused notion of spatiality. This project led Bergson toward important contributions in rethinking fundamental questions of consciousness, perception, and representation. For example, *Matter and Memory* (1896 [1991]) offers a bold account of experience from the perspective of duration – Bergson’s nonspatial conception of time. Here the notion that consciousness presides over and elaborates representations of reality is demonstrated to be an illusion that masks the dynamic way in which experience is an emergent property of a distributed network of components that includes brains, bodies, and worldly materials. By *Creative Evolution* (1907 [1998]), Bergson had firmly placed psychological questions within a broader ontology centered around the *élan vital*, the creative unfolding of life through its myriad actualized forms. His final work *The Two Sources of Morality and Religion* (1935 [1977]) provided a long-promised contribution to moral philosophy which linked the development of human relations to a broader process ontology of intersecting open and closed systems.

The breadth and significance of his work was widely acknowledged within his lifetime. William James engaged deeply with his work, and the reciprocal influences between these two thinkers of “radical empiricism” are clear (see James 1909; Bergson 1992, 2002). From 1900, Bergson held the prestigious chair in ancient philosophy at the Collège de France, before transferring to the chair of modern philosophy in 1904. His public lectures at the Collège were “must-see” events for both intellectuals and fashionable high society (see Lundy 2018: 2). When Bergson visited the University of Oxford in 1911 and Columbia University, New York, in 1913 there was widely reported talk of a “Bergson craze” and “the Bergson Cult” (McGrath 2013). Given this, it is not surprising that Bergson’s influence is to be found not only within philosophy, but also upon the majority of the major thinkers in psychology and other social sciences of the time. Jean Piaget, for instance, experienced reading Bergson as a “profound revelation” that knowledge and morality were immanent to life itself (Vidal 1994). Although politically and institutionally often opposed, Émile Durkheim’s work shares many of Bergson’s concerns to overcome the imprecision of conceptual analysis and with placing epistemological questions within an immanent account of the emergence of sociality (Lefebvre and White 2010). Famously, Maurice Halbwachs’ (1980, 1992) groundbreaking work on collective memory was an attempt to navigate a course between the intellectual poles of Bergsonism and Durkheimian sociology.

Yet Bergson’s influence was to wane. By the middle of the century, Bergson’s work had fallen out of favor, with his actual works often dismissed by drawing upon the caricatured ideas of popularized Bergsonism (Lundy 2018). In part, this is because many of Bergson’s claims – such as the idea of “retroactive possibility” – are highly obscure when considered outside of the complex weave of his thinking. This has led to the unfortunate situation where those of Bergson’s contemporaries and successors whose ideas were in dialogue with his own have become similarly misunderstood. For example, Mary Douglas’ introduction to the English version of Halbwachs’

La Mémoire collective (1950 [1980]) claims that the work is entirely in opposition to Bergson despite Halbwachs' account of experience as a resonance between group members whose intelligibility relies substantively on Bergsonian notions of multiplicity and overlapping durations (see Middleton and Brown 2005).

The late twentieth century was marked with a surprising resurgence of interest in Bergson. This was largely driven by the work of Gilles Deleuze, who wrote and thought extensively with Bergson, principally in the monograph *Bergsonism* (1966 [1991]) and the two volumes of *Cinema* (1983 [1986]; 1985 [1989]). More broadly, several of the most significant concepts and themes in Deleuze's philosophy can be traced back to his engagement with Bergson, including the virtual/actual and multiplicity (Lundy 2018), which has in turn compelled scholars working on and with Deleuze to rediscover Bergson. While it is common for Bergsonians to remark that Deleuze's reading of Bergson is unorthodox if not unfaithful (see Gunter 2009), there is no denying that this conduit has led to a renaissance of engagement with Bergson's philosophy. In so doing, Bergson has come to be recognized as occupying a pivotal place within what can be loosely called "process thought" – a category that typically includes thinkers such as Alfred North Whitehead, William James, Gilbert Simondon, Isabelle Stengers, and Deleuze himself.

Many of the conceptual challenges of understanding Bergson's unique vision around themes such as possibility, creativity, intuition, and memory become far more tractable within a "process ontology" of emergence, multiplicity, and distribution. For example, much of the confusion around Bergson's so-called "psychologism" arises from confusion around how he uses the term "intuition." This is usually understood as a form of knowing that arises within the individual, based on prior experience rather than formal knowledge. But Bergson neither treats consciousness as synonymous with a self-contained psychological subject, nor restricts experience to a purely psychological or individualistic usage. Intuition is primarily a form of relationality within duration itself, rather than between clearly defined subjects

and objects. Similarly, Bergson's notion of memory cannot be apportioned between the terms "individual" or "collective" but is better understood in process terms as the dynamic reinvention of the past in present action that momentarily actualizes or recreates relations between "subjects" and "objects" in the course of its emergence.

Bergson on "The Possible" and "The Real"

To understand Bergson's treatment of the possible, it is first necessary to engage with the broader metaphysical arguments at work in his philosophy, in particular the relationship between "the possible" and "the real." The notion of the possible plays an enormously important role in shaping experience. It is used by conscious actors on a regular basis to navigate and make sense of reality, from the mundane planning of daily activities to our more grandiose reflections on the future and the past, both personal and collective. But what is the nature of the possible and possibilities, and how does this differ from that which has been "realized"?

It is commonplace to think of the possible and possibilities in a Platonic fashion, whereby the various possibilities of what could occur (or might have) exist in an "ideal form," some of which will be (or were) selected. In contrast to this orthodoxy, Henri Bergson claims that the possible is merely "the mirage of the present in the past" (1992: 101). Given that this comment goes against the "common sense" understanding of the possible, accepting Bergson's position will be immensely challenging; but if he is correct then major implications ensue for how we conceive of life and reality – implications that could impact not only our cosmological understanding but also everyday existence.

In 1920 Bergson delivered a lecture at Oxford titled "The Possible and the Real." As he notes at the beginning of this lecture, Bergson's thoughts on the possible are a by-product of his other investigations on the nature of time, freedom, action, and creativity. The shared concern of

these other studies is stated by Bergson as follows: “the continuous creation of unforeseeable novelty which seems to be going on in the universe” (1992: 91). Put in simple terms, Bergson is of the view that the future is open and cannot be reduced to what currently exists. Moreover, the movement of reality is one of “global and undivided growth, progressive invention, duration: it resembles a gradually expanding rubber balloon assuming at each moment unexpected forms” (1992: 96).¹ As this image suggests, reality and its experience does not involve charting a path through a multitude of ideal options that are sequentially selected. Instead, reality *unfurls* itself in time and space. When this happens, it is not as if the universe increasingly fills up an absolute vacuum, for there is no void beyond the universe that predates its reality. In the same way, presuming that possibilities predate their realization would involve postulating a metaphysical framework in which “all is given” and time does nothing, since the future on such a schema essentially becomes nothing more than a complicated combination of what currently exists. An epistemology that assumes the preexistence of ideal possibilities is thus incompatible with a metaphysics that allows for genuine change and the emergence of the new.

To flesh out this point Bergson recounts a conversation in which he was asked to predict the future possible direction of literature. It is mistaken, he says in response, to conceive of future works “as being already stored up in some

cupboard reserved for possibles” (1992: 100). Instead, “the work of which you speak is not yet possible. [...] I grant you, at most, that it *will have been possible*,” for it is only once the work of art has been created that it is real, “and by that very fact it becomes retrospectively or retroactively possible” (1992: 100). Bergson is quick to qualify here that he is not advocating a theory of reverse causality, in which the present ontologically produces the past; it is the possible that is placed in the past, not the real. Possibility, therefore, does not precede reality, if one means by this that the possible exists prior to the real. Rather, something becomes possible only once it is real, but when this occurs the possible is retrospectively posited as being prior to the real, so that the possible “will have preceded [the real] once the reality has appeared” (1992: 101).

We can now start to see how the possible for Bergson is a “trick of the mind,” an epistemological illusion derived from a false metaphysics. When something occurs, it is natural for the intellect to surmise that it was possible for that thing to occur before it indeed occurred. However, just because the possible is retrospectively posited by the mind as preceding the real does not mean that possibilities *prospectively* preexist a reality that will come to be (or not). When something occurs, we know for a fact that it was possible to occur. But it does not follow from this that we can know what might possibly occur in the future. Between these two configurations are two different senses or kinds of possibility. In the first case, “possible” is said in the sense that “there was no insurmountable obstacle to its realisation” – i.e., it was not impossible – and “this non-impossibility of a thing is the condition of its realisation” (1992: 102). This “negative” sense of possibility, however, is quite distinct from the more “positive” sense in which the form of possibilities are ideally preexistent: “If you close the gate you know no one will cross the road; it does not follow that you can predict who will cross when you open it” (1992: 102).

As this quote indicates, Bergson’s critique of the possible is more exactly a critique of the “positive” sense of the possible that is commonly employed, whereby one imagines various ideal

¹ See also the opening of *Creative Evolution*, where Bergson says: [T]here is no feeling, no idea, no volition which is not undergoing change every moment: if a mental state ceased to vary, its duration would cease to flow. Let us take the most stable of internal states, the visual perception of a motionless external object. The object may remain the same, I may look at it from the same side, at the same angle, in the same light; nevertheless the vision I now have of it differs from that which I have just had, even if only because the one is an instant older than the other. My memory is there, which conveys something of the past into the present. My mental state, as it advances on the road of time, is continually swelling with the duration which it accumulates: it goes on increasing – rolling upon itself, as a snowball on the snow. [...] The truth is that we change without ceasing, and that the state itself is nothing but change. (1998: 1–2)

forms of reality before they become reality (or fail to). His claim is that such images are reflections of the real, of the reality that already exists, just as the image of a person in the mirror is a reflection of a real person, not a possible one lacking reality. The “positive” notion of the possible supposes that there are various distinct options laid out before us, like hollowed outlines, one or some of which will “become reality by the addition of something, by some transfusion of blood or life” (1992: 101). But this manner of thinking is wrong-headed – or to be more precise, it involves a confusion of the “more” with the “less.” Contrary to the suggestion that the real is the possible with existence or being added to it, Bergson contends that there is more in the possible than in the real. In his words:

[T]he possible implies the corresponding reality with, moreover, something added, since the possible is the combined effect of reality once it has appeared and of a condition which throws it back in time. The idea immanent in most philosophies and natural to the human mind, of possibles which would be realised by an acquisition of existence, is therefore pure illusion. One might as well claim that the man in flesh and blood comes from the materialization of his image seen in the mirror, because in that real man is everything found in this virtual image with, in addition, the solidity which makes it possible to touch it. But the truth is that more is needed here to obtain the virtual than is necessary for the real, more for the image of the man than for the man himself, for the image of the man will not be portrayed if the man is not first produced, and in addition one has to have the mirror. (1992: 101–102)

The confusion of the more and the less, as it turns out, lies at the heart of several other metaphysical mistakes identified by Bergson. It would appear obvious to many that there is *less* in nothing than something, *less* in disorder than order, but Bergson argues that the converse is the case: “there is more intellectual content in the ideas of disorder and nothingness when they represent something than in those of order and existence, because they imply several orders, several existences and, in addition, a play of wit which unconsciously juggles with them” (1992: 99). If it is often assumed that there is more in something than nothing – more in order than disorder, and more in the real than the possible – it is because we have a

tendency to start in the wrong place. If one starts with nothing, or with nonbeing, then it would seem self-evident that a thing or being is more than nothing or nonbeing. A simple glance at these words written down on paper, however, alerts us to Bergson’s point: the word “nonbeing” is based on the word “being,” it is “being” with three letters tacked on the front, just as “nothing” is “thing” + “no.” What this indicates is that nothingness and nonbeing, as with disorder and the possible, are all predicated on something, some being, order, or reality. There is thus more in nonbeing than being, more in nothingness than existence, and more in the possible than the real, for in each case the former relies on the latter, along with the idea of negation and the mind that abstractly posits it. The real, in short, comes first, and if there is such a thing as possibility, “it is the real which makes itself possible, and not the possible which becomes real” (1992: 104).

A Bergsonian Social Science of the Possible?

In the televised dramatization of M.R James’ short ghost story *Whistle and I’ll come to you, my lad* by Jonathan Miller, the central character, Parkin, a Cambridge professor vacationing at a seaside guest house, is challenged by another guest to apply his philosophy to explain the supernatural with the rhetorical statement “But there are more things in heaven and earth than in your philosophy.” With some amusement, Parkin replies “I would prefer to put it a different way – there are more things in philosophy than are dreamt of in heaven and earth.” Parkin might be seen as a caricature of a philosopher such as Bergson who develops a complex and convoluted metaphysics to explain the nature of existence. But this belies the extent to which Bergson is, above all else, a philosopher who is attuned to “lived experience.” For Bergson, philosophy must follow the contours of life in its emergence. We must not be forced to make the choice into which Parkin is lured between the focusing on either the actions we take as part of worldly engagements or the philosophical discourse in which they are to be

understood. Rather philosophy must be cut from the cloth of living, lest its concepts become akin to a “pile” of “ready-made garments” which are placed on life (Bergson 1992: 175). Bergson’s account of possibility is a systematic attempt to understand lived experience as an emerging, self-organizing pattern which is not determined by preexisting possibilities, but rather articulates the conditions of its own emergence retroactively in the process of constituting itself. But in so doing, we intuit that the pattern of our unfolding lived experience is accompanied by a virtual image that shows that there are other potential patterns, that the actuality of living creates its own sense of the possible.

The challenge of Bergson’s thinking is to develop an account of social action and psychological life in these terms as emergent patterns rather than the reproduction or realization of pre-existing possibilities. A major obstacle to this is the deeply ingrained tendency within social science to begin with a “substance” account of particular matters in hand. For instance, much social theory remains committed to the idea that there is something like a “generative mechanism” that underpins both social structures and individual agents, which is ultimately responsible for the particular forms that they take. Similarly, psychological theorizing typically relies upon a notion of the subject or self that becomes progressively realized through its actions. But for Bergson, there is no mechanism or “thing” that presides over actions other than the self-generating forms that express the dynamic of the *élan vital*. As he puts it we must grasp that “there is *more* in a movement than in the successive positions attributed to the moving object” (1998: 316) and treat lived experience as rooted in a reality which “no longer appears as finite or infinite, but simply as indefinite. It flows without our being able to say whether it is in a single direction, or even whether it is always and throughout the same river flowing” (1992: 211).

Clearly this raises significant challenges to forms of social science which treat identity and continuity over time as grounded in a substance ontology. The psychology of memory, for example, classically views past and future from the

perspective of a present that consists of the automatic storing of present moments into organized memories, which in turn informs the anticipation of future presents which are in the process of being realized (see Middleton and Brown 2005). While the field has moved on considerably from the “storehouse” model which Bergson so thoroughly critiqued in *Matter and Memory*, it still relies upon some notion of there being an agent, in the form of a set of bounded processes that ultimately map onto patterns of neural activation, which underpin experience. This is yet another instantiation of the idea that life gains its fullness in the present moment, which is harvested from an admixture of realized past possibilities and vague futures hitherto lacking in content. Only the present moment is truly “real.” While the approach seems to overcome the apparent vagueness of the notion of the real as akin to a river which is neither “finite nor indefinite” and never identical to itself, it substitutes for it endless conceptual puzzles, such as the difficulty of defining the limits of the present moment, the point at which the past has been successfully restored (i.e., when memory is recollected) and the future properly arrives (i.e., when imagination becomes reality).

The alternative which Bergson offers is to begin analysis by thinking in terms of time rather than space. Duration, or time as it is lived, is fundamentally indivisible. It is not possible to clearly distinguish the present from the future into which life is becoming, nor the past from which it emerges, in the same way that the listener of a piece of music is not fixated on a particular note or sound, but instead caught up in the passage of the music unfolding. The river example is only confusing when it is thought in terms of defined spatial categories – this section and that section – whereas from the perspective of time, the reality of the river as flowing in ways that are neither entirely determined nor undetermined is clear. Identity comes from the particular manner of its flowing, rather than a homology between different spatially organized parts. The alternative which Bergson provides is to affirm that memory and imagination – the two terms essential to thinking the real and the possible – are fundamentally

temporal categories which require treatment as such rather being confused with space. For instance, it is possible to conceive of variations of speed and rhythm in relation to memory, recollections that emerge slowly or those that appear almost instantaneously, those that routinely punctuate our daily lives versus those arise only irregularly (Brown and Reavey 2015). Similarly, imagination could be considered in terms akin to the “varieties” of experience to which William James referred, where some forms of imagination overlap with or interrupt one another, while other diverge.

Thinking in time overcomes some of the tendencies to bind experience to a particular spatially defined “thing” (e.g., agent, structure, person, and other). The timing of lived experience is never entirely determined by the “subject” of that experience, it is intertwined with and shaped by a multitude of timings. For example, human lived experience is composed of an array of rhythms and cycles including biological (e.g., circadian, nutritive, and respiratory), psychological (e.g., perceptual, affective, and attentional), and social (e.g., clock time, the working day, and age markers), which interact with one another to create complex and often conflicting patterns of temporal flow. Indeed, it is precisely in order to manage these tensions within living time, Bergson argues, that we have learned to objectify time as space. Breaking experience into distinct segments – a process Bergson refers to as the “cinematographic mechanism of thought” – allows for a form of practical mastery over the world. The objectification of nutritive cycles into distinct “meal-times” allows them to be managed in a way not unrelated to the way that the organization of the working day allows for maximum value extraction from labor. Frederic Worms (2017) argues that Bergson’s work demonstrates a tension between the “critical” (the establishing of limits and distinctions) and the “vital” (the emergent patterning of life). Life is not unconstrained, but is always responding to variations formed within and between the actions of living organisms – “life responds to life” (see Brown and Reavey 2019). An analysis of memory and imagination needs to grasp the ways in which lived

experience becomes objectified within its emergence.

Middleton and Brown’s (2005) work develops a social psychological approach to remembering in this way by inverting the problem of memory. They argue that from the perspective of Bergsonian duration, the retention of memories is a non-problem. If duration is indivisible, then the past is never disconnected from the present, it does not “go anywhere.” What instead requires analysis is the ways in which the entirety of the past does not weigh at every moment on current actions. In other words, it is the setting aside or provisional “forgetting” of the past that needs to be understood. While Middleton and Brown’s analysis draws extensively on the Bergson’s account of needs as guiding this selection of memories, they turn to Halbwachs for concepts to describe the “projecting,” “collecting,” and “objectifying” of experience in material forms. In a similar fashion, Stenner’s (2018) work on imagination and fabulation draws heavily upon Bergson’s account in *The Two Sources of Morality and Religion*. The problem, for Stenner, is to understand how liminal experiences, the moments “betwixt and between” distinct phases of psychosocial life, are managed during the process of their transition. To undergo such transition is to find oneself between a past that is in the process of withdrawing and a future that has not yet properly arrived. Transitions are always risky, a potential threat to psychological well-being and social cohesion. Stenner describes how Bergson deals with this issue by splitting the category of imagination into two distinct processes. One is that of “myth-making” or “fabulation,” which involves the creation of “false images” that have such apparent solidity that they create a bridge across the liminal phase. The other is a form of creative “mysticism” that invents new and dynamic images that transform the nature of the division between past and future. This creates a contrast between an active or open form of imagination, and a more passive or closed form. While this enables Stenner to point toward different modes of engaging with liminality, he turns toward Whitehead for a conceptual vocabulary to clarify the ways in which experience is objectified in the dynamic relationship between

these two forms of imagination. The outcome of both of these approaches is that when developing social science applications of “thinking in time,” Bergson’s work is usefully augmented by turning toward other thinkers.

To conclude, the key elements of building upon Bergson’s account of the possible and the real are as follows. Analysis needs to be closely fitted to the forms of lived experience that require understanding. The method to achieve this outcome is thinking from the perspective of time rather than spatiality, and correspondingly, the process of creation rather than what is created. Possibility is treated as retroactively constituted in the process of action rather than the conditions upon which it is realized. There is always “more” in the virtual image than in the actuality which it reflects. Past and future are not divided from present, but are aspects of its emergence, and as such are no less real, although they do not have a causal relationship to current actions. Imagination and memory are two descriptions of the process of intuiting the emergent patterning of lived experience. While lived experience is continuously objectified as part its emergence, this does not halt or divide the process. Rather, experience is itself the perpetual process of creative emergence and self-objectifying as life responds to life.

The Possible in the Life and Work of Jacques Lacan

Duane Rousselle
Sociology and Psychoanalysis, The School of
Advanced Studies, University of Tyumen,
Ontario, Canada

Abstract

This entry explores the contribution that Jacques Lacan made to the topic of the possible. For Lacan, it is more important to centralize a discussion of the impossible as a mode of

subjective causation. This entry traces a lineage of three periods of thinking the impossible in the work of Jacques Lacan.

Keywords

Jacques Lacan · Psychoanalysis · Impossible · Radical theory · Revolution

Modalities of the Impossible

Graffiti discovered in Paris during the infamous uprisings of 1968 reveal a welcomed slogan for the European revolutionary left: “be realistic, demand the impossible.” The continued popularity of the slogan no doubt results from a counter-intuitive punch: the utopian linkage of impossibility with realism. When these two signifiers – the impossible/impossibility and the real/realism – are brought together, do they not strike a blow against conservative orientations that equate realism only with what is possible? The slogan also laces impossibility with problematic utopian sentiments, thereby betraying the overarching aspiration for change. Revolutionary discourse such as this often finds itself anchored to an imagined model of utopia. The object of such an anchorage, forever out of reach, breeds impossibility. We should juxtapose this position with that of former American democratic presidential candidate, Elizabeth Warren. When John Delaney accused Warren of running on a platform of “impossible promises” (in other words, of participating in a politics of “impossible demands”) she responded: “I don’t understand why anybody goes to all of the trouble of running for president of the United States just to talk about what we really can’t do and shouldn’t fight for” (Biography.com 2019). This statement positioned Warren as a pragmatic voice of reason with respect to the topic of impossibility, or, put another way, at this moment she fully secured for herself a platform of “measured alternatives” to Bernie Sanders.

An interesting taxonomy of the (im)possible presents itself. Whereas the revolutionary sentiments of 1968 appear to us as “impossible impossibilities,” that is, they appear to us as ideals demanded so that they may never be reached,

the political oppositions of the 2019 presidential race demonstrate that sometimes “impossibilities” also become rendered as “possible.” Through her rejection of Delaney’s realism of “possible possibilities” – whereby the focus is on obvious and attainable political goals that remain within the scope of existing political praxis – Warren positioned herself as the pragmatic alternative to Sanders’ apparent platform of “impossible impossibilities” (whereby “impossible impossibilities” exist without any reference to the possible). We have, therefore, the following categories: “impossible impossibilities,” “possible impossibilities,” and “possible possibilities.” Are we not missing the category of the “impossible possibilities?” The domain of “impossible possibilities” pertains to nonutopian perspectives concerned with unearthing prior determinations within any linkage of (im)possibility with realism. Hence, a key political question that those who adhere to “impossible possibilities” might ask follows: “Are we not confined to the basic operations of the overarching political system even (and especially) during our efforts to position ourselves (impossibly) outside of it?”

This is the problem with Todd May’s so-called post-anarchist political philosophy (see May 2005). May positions his argument in the following way: political philosophers cling to one of two poles: (1) reality (the “is,” explored often through metaphysical speculation), or (2) morality positions bordering “utopia” (the “ought,” explored often through normative or meta-ethical argumentation). Post-structural anarchism rejects any hard-headed decision regarding which pathway is best to take and proposes an altogether more troubling solution which consists of situating oneself within the tension between the two. The move shifts attention from grand strategic political gestures (e.g., revolutionary politics) toward tactical engagements across a variety of scales and nodes. We should repurpose the logical critique made in another context by Margaret Archer (2008): central conflation occurs when thinkers either consolidate or else avoid altogether problematic binaries by concealing the inherent and incessant rupture or division which precisely defines that binary. Thus, when we believe that a binary is at play

what we are actually witnessing is not a polarity (e.g., of “structure” and “agency” or of “reality” and “utopia”) but rather a rupture between the one and its limitation or excess (see Žizek 2019). May’s apparent even-handedness therefore conceals the fact that the “is” exists precisely as the incompleteness of the “ought,” or, put another way, the “ought” contains within itself a fundamental and irreconcilable kernel of trauma.

The point is not to side-step the problem of the binary – which is what all aforementioned discourses on impossibility intend to do – but it is rather to find what within reality compels the subject toward the “ought” in the first place. If the “ought” exists with a fundamental limitation then so too does the “is,” since it is from the impossibility of the real that any utopian possibilities emerge. The ethical project of psychoanalysis is to articulate and explore the scope of the subject’s compulsion toward truth via the urgency of these prior impossible determinations. If speech occurs within the context of a prior determination, then this is because it is an action situated within an overarching discourse. Our task as psychoanalysts is to inquire into the situatedness of the subject in relation to the various determinations resulting from permutations of a master discourse (whether that discourse be traditional, whereby the subject puts him or herself into the position of producing knowledge out of the non-sensical utterances of a master, or it is the latest capitalist mutation, whereby the subject suffers from direct engagements with *jouissance*). It is well known that a master discourse defines the basic contours of political expression (and that this in some way is the prevailing understanding of what is meant by ideology). As such, the subject is always split by this discourse which determines and compels him, split, that is, between what Lacan named the “subject of the statement” (e.g., what the subject intended to express as the content of some information or knowledge) and the “subject of enunciation” (e.g., the unconscious truth, revealed through distorted speech). We should go a step further: the master discourse defines not only the possible but also more cunningly the very space of impossibility. Rendered into Lacanian language we might claim that the subject remains trapped by a

master signifier, which defines the scope of his fundamental fantasy (utopia), but without that primary signifier a far worse future awaits (e.g., the death of subjectivity). To traverse the fundamental fantasy involves not only the destruction of that orienting signifier but also more essentially the reinvention of the entire symbolic universe along with its space of impossibility.

Instead of retreating into the space of political fantasy and the realism of pragmatic possibilities whereby the impossible becomes rendered through the prism of prevailing politics, Warren could have agreed with Delaney’s characterization of her political agenda. Moreover, she could have rebutted by articulating the fact that Delaney’s “possible possibilities” are determined by prior “impossible possibilities.” Incidentally, is it not the case that all three of the concepts (possible possibilities, impossible impossibilities, and possible impossibilities) are determined first of all by impossible possibilities? All positions are grounded upon fundamental impossibilities – recall that Freud described politics itself as one of the impossible professions – and are determined by the necessity of forming possibilities out of systemic limitations. The problem with all discourses of possibility – especially of possible possibilities – is that they neglect entirely the domain of impossibility. Similarly, the problem with discourses of possible impossibilities is that they flee from the anxiety of any direct confrontation with the impossible by seeking temporary refuge in prior comforts. Finally, the problem with impossible impossibilities is that they elevate impossibility to an ideal and thereby produce failure as the only goal.

If “possible impossibilities” seek comfort in prior political positions, then “impossible impossibilities” seek comfort by restricting self-responsibility for any possibility. The latter seek disengagement and appear to us like the critic who so easily dismisses the work of others but resists ever proposing something that another person will also critique. Take Anton Ego’s final statement of self-criticism in the animated movie *Ratatouille*:

In many ways, the work of a critic is easy. We risk very little, yet enjoy a position over those who offer up their work and their selves to our judgment. We

thrive on negative criticism, which is fun to write and to read. But the bitter truth we critics must face is that in the grand scheme of things, the average piece of junk is probably more meaningful than our criticism designating itself so. But there are times when a critic truly risks something, and that is in the discovery and defence of the new. The world is often unkind to new talent, new creations.

We should be very careful here: Anton Ego was not blindly celebrating the new as the product of a self-conscious inventor. Rather, in the next few sentences he celebrates the work of Linguini, who, through his subtle invention, reintroduces the importance of a traditional “peasant” dish, linguini. In this case, the new is linked with realism and impossibility through the assertion and exposition of prior determinations as such. Linguini is the dish of the humble, and it is described by the critic as if it were a “low class” food. Yet, the food, which was previously ignored by the prevailing culinary arts establishment, was forced into a context which was not prepared to accept it. In light of this, we should ask ourselves the following: If the problematic discourses on (im)possibility are to be avoided, what is the alternative?

The revolutionary slogan of 1968 elevates impossibility to an unreachable ideal, Warren’s position degrades impossibility by rendering it once again through the prism of pragmatic possibilities, but Sanders’ position of supposed “impossible impossibilities” is also constantly degraded into “possible impossibilities” by way of its situatedness within the existing political apparatus. Bernie must nonetheless appeal to existing political infrastructure in order to discuss his brand of socialism. What he offers is a dangerous transformation of the Marxist political project: by subjecting the revolutionary aspiration to populist attitudes and electoral democratic legitimization, does he not, from the standpoint of the future, demonstrate that even socialism is possible within the existing democratic capitalist framework? It is useful to reiterate Alain Badiou’s distinction between “democratic materialism” and “materialist dialectic”: whereas the first proposes that every possibility exists within the political apparatus and that those which do not can nonetheless be made to conform, the latter proposes that there is something – truth – which is

fundamentally and stubbornly “impossible.” Thus, we should be prepared to admit that Warren’s platform is the natural outcome of the eventual structural position of Sanders.

As for the revolutionary slogan, there is the problem that Lacan sought to address during his visit to the revolutionary students of France: “as revolutionaries, what you aspire to is a master . . . you will have one!” (Lacan 2007, p. 237). Lacan revealed how the linkage of impossibility with realism produces a more deceptive (and therefore more insidious) perpetuation of the discourse of mastery. The warning he issued to subjects of revolutionary discourse was that all discourses of (im)possibility have within them a hole. Or, to put it in more technical terms, he exposed the “inexistence of the Other.” Yet, the inexistence of the Other does not at all keep the discourse from supplying the subject with the very frame of impossibility. Ideological discourse does not consist in propagating the terms of possibility, then, because the move is much more radical: the discourse of mastery produces the very space of impossibility, without which the revolutionary slogan remains impotent. Any attempt to hold the master to account only demonstrates all the more the dependency of impossibility on discourse such that the hysterical political subject becomes trapped within a fundamental deadlock. It follows that all possibilities, pragmatic or otherwise, exist as the content of any political strategy within the overarching impossibility which gives politics its true mandate. What we name “political strategy” is therefore nothing more than an attempt to outrun this “hole,” to fill it in with fresh possibilities. Or, put another way, political strategy is the name we give for any subjective escape from the dupery of politics (“there are no honest politicians!”) since, as Lacan claimed, the non-dupe always errs.

The very term revolution implies already that political strategy is always a sort of algebra of the slave. Indeed, Lacan claimed that any revolution is only a counterclockwise turn of the master discourse. The ingenuity of the discourse is precisely to keep itself from offering “impossible” solutions, utopian answers, so that the subject will continue to request them. If these impossible

solutions were fully articulated, the discourse would cease to function. Therefore, paradoxically, it is because of the inexistence of the Other that his or her power remains all the more secured. Lacan made a radical move here by insisting that psychoanalytic discourse provides the only counterpoint to discourses of mastery because it alone engages the latent and determinative dimension of discourse, and it alone reveals the inexistence of the Other along with the fact that we cannot escape being a dupe. At some point it becomes obvious that the latent dimension of discourse is split between symbolic determinations (e.g., the hidden ideological content, such as those described methodologically by Roland Barthes in his “cultural semiology” or “second order sign system”) and a real traumatic hole (which never ceases to interrupt meaning). There is at this level only “something,” that is, the signifier, and “nothing,” that is, *jouissance* as such, and at the convergence of something with nothing there is a radical impossibility of relation.

The revolutionary slogan remains quite far removed from analytic discourse in that it avoids this substratum of political impossibility. Instead, the slogan affirms an imperative of demand: “. . . demand the impossible!” It cannot speak of the possible as an emergent and necessary property of the impossible because it has as its point of departure the demand to avoid the possible to the greatest extent possible, and to avoid, therefore, the possibility that one is all the more determined by those various possibilities. It cannot (and will not) recognize that the linkage of realism with impossibility is a product of the discourse of mastery and that it affirms the existence of the Other. Indeed, the very form through which any demand is articulated demonstrates all the more a discursive dependence upon the Other, and it elevates or centralizes the Other as a lynchpin of discourse which secures the possibility of there being “impossible impossibilities.” Thus, we might claim that all discourses are discourses of utopia, since utopia is the idealized or imaginary non-place, or what Lacan referred to as *objet petit a* as semblant. Put differently, adherents of the revolutionary slogan are not at all prepared to admit the inexistence of the Other, and so they go on

issuing demands precisely to convince themselves of mastery.

But there is another interesting remark to be made about the impossibility of utopia. Within the anarchist political tradition, the word utopia was often a bad word. For example, Larry Gambone argued that Petr Kropotkin and Pierre-Joseph Proudhon were against utopia because it projected an ideal and hence restricted personal liberty. But wouldn't the more interesting reading be precisely the opposite? What if Kropotkin was against utopia not because it was “too violent” of an ideal but rather because it was not violent enough? The problem with revolutionary anarchism in this case would be that it avoids the altogether more troubling possibility that utopia proposes a version of impossibility which can still be rendered comforting within our imagination. Hence, it misses the true impossibility: that human political communities are defined by what Georges Bataille named the principle of heterogeneity or “general economy”: an inescapable violence that overflows into the life world of humanity. In other words, utopia misses the dimension of the Lacanian death drive as that which pushes forth with or without the articulations of political strategists.

There is therefore a problem of death drive alongside a problem of demand. It was the Canadian sociologist Richard J. F. Day who demonstrated this problematic logic of demand among the revolutionary (mostly anarchist) left very well when he argued that the “new social movements” erect a discourse of demand such that the Other (e.g., the governmental State) is presupposed as the recipient of that demand. The problem for Day was that he affirmed, in place of the politics of demand, an altogether more troubling and idealized “politics of affinity.” I have argued elsewhere that this logic avoids the difficult and violent work of revolutionary politics in favor of a long waiting game (see Rousselle 2017). They missed Rosa Luxemburg's important point: if we wait for the appropriate revolutionary moment, we will forever miss the appropriate revolutionary moment. In any case, the Other exists in anticipation of any response to a demand, and political strategy exists to describe the content of any such demand but not

the fact of demand as a form of prior subjective determination. In this way, the Other's structuring influence becomes repetitively secured. One must therefore avoid the following three modalities of (im)possibility: (1) utopian/hysterical revolutionary haste ("impossible impossibilities"), (2) liberal pragmatism ("possible impossibilities"), and (3) conservative orientations which accept only existing possibilities ("possible possibilities"). The analytic discourse teases out the fourth domain of "impossible possibilities" as the domain of prior determinations and retroactive political causation as the only exit from the discourse of mastery.

Real Impossibilities

Three moments are worth highlighting in Lacan's teaching on the impossible. First, there is the "early period" of the 1950–1960s which was marked by a movement toward the discovery of the real as a failure or glitch in the processes of imaginary identification. Multiplicities, in the form of the fragmented body ("organs without a body"), threaten any imaginary coherence of the subject's self-image. The second "middle period" of the 1960–1970s exemplified a logical articulation of the real, particularly through the Aristotelian categories of *automaton* and *tuche*. Lacan's most noted students (the circle surrounding Jacques-Alain Miller and Yves Duroux) were busy exploring the real within the what they named "logician's logic." The logician in question was Gottlob Frege, and the logic discussed in his *Foundations of Arithmetic*. During this period Lacan explored the limits of repetition as "real," and, derived the following axiom: the real is that which resists symbolic repetition, absolutely. In the final "late period" of the 1970–1980s, the real was situated as "that which never ceases to not be written." Each period explored the real in relation to another order: first, imaginary; second, symbolic; and, third, real. The first period discovered the real in the fragmented image, the second period located a space of the real that exists in some relation to the installation of a primary symbolic element (what Lacan named the "Name/No

of the Father"), and the final period centralized the experience of the real in relation to the jouissance of the drives (Scheme 1).

Put another way, the final period introduced "impossibility" as a mode of stabilization for a subject immersed in jouissance. The impossibility is grounded fundamentally in a non-sensical symptom Lacan named the *sinthome*. But we should return for a moment to the first period, when there was an awareness of the imaginary as an obstacle to any revelation of symbolic unconscious truth. We see this most clearly in the "L Schema," which demonstrates two fundamental axes: on the one hand, there is the imaginary axis of transferences, which occludes the second latent symbolic axis of unconscious truth (see "L Schema" above). After the seminar of the "L Schema," there is its adaptation into an "R Schema" (see "R Schema" below). The latter delimited the real by producing what appears to be a topological surface (rather than a "flat" flow chart). Nowhere is Lacan's "return to Freud" more apparent than during this period: the classical Freudian unconscious as a written surface to be deciphered by the analyst remains fundamentally intact. A wonderful formulation suddenly appears: the real is "impossible." Toward the end of this period the real obtains the status of that which resists symbolization (Lacan 1991, p. 66). All discourses and aesthetic regimes must contend with radical impossibility. Lacan was therefore not a utopian dreamer of the "possible" but rather a thinker in confrontation with the real as impossible (Scheme 2).

In Lacan's 11th seminar, *The Four Fundamental Concepts of Psychoanalysis*, there are further developments to this conception of the real. A classical opposition, extracted from Aristotle, between *automaton* and *tuche*, was explored. The category of *tuche* was related to the concept of the real as an impossibility inherent to the repetition *automaton*. But *tuche* is not itself another concept for the real but is rather the subject's "encounter with the real" (Lacan 1998 [1964], p. 52). This thereby demonstrates the centrality of the subject vis-à-vis impossibility. The subject encounters impossibility through an interaction with the *objet petit a*, that elusive object

The Possible in the Life and Work of Jacques Lacan, Scheme 1 Lacan's "L Schema"

The Possible in the Life and Work of Jacques Lacan, Scheme 2 Lacan's "R Schema"

cause of his desire, which, because it is a lost cause, appears to him as a semblance. Any encounter with the real occurs beyond the network of signifiers, beyond meaning and imagination, beyond comprehension. It is only here that the subject's relationship to his or her cause is discovered (ibid., 54). Traditionally, the network of master signifiers reveals itself through the difficult work of analytic work with the symbolic unconscious (the unconscious is believed here to be

made up of "symbolic stuff"). No wonder Lacan often claimed that the unconscious was structured like a language (although in his "late teaching" he clarified that this does not mean that it is structured "by" language).

It would seem that Lacan's understanding of the unconscious underwent a transition or a shift of emphasis. Whereas the unconscious was once reducible in some sense to its various symbolic inscriptions, the real as impossible was eventually thought to exist as a primordial and inescapable wound. Transference is a repetition only because it is a problematic attempt to escape the traumatic wound of subjective impossibility. Hence, there are at least two repetitions: on the one hand, there is a pathological repetition revealed through the transferences, and, on the other hand, there is the repetition of the drives always returning to their place within the real. Following Lacan, we should characterize *tuche* as trauma: "[t]he function of *tuche*, of the real as encounter [. . .] first presented itself in the history of psychoanalysis in a form that was in itself already enough to arouse our attention, that of trauma" (ibid., 55). An encounter with trauma, though, is not itself the thing of trauma: it is the opening up of a traumatic space within the imaginary and symbolic world of the

subject. It is an opening of oneself to the traumatic space that was already troubling the subject anyway, a widening of that space within the symbolic and imaginary coordinates of the subject's everyday life.

A similar logic occurred in Freud's work when he constructed the apparent opposition of the reality and pleasure principles. There was thought to be something "unassimilable," indeed something traumatic, at the heart of this oppositional pair. During the interplay of pleasure and reality something of the pleasure is endlessly preserved, and this something is the inescapable trauma of being itself. The subject secures for itself a place within the repetition of the symbolic chain. Lacan's words resonate (I am tempted even to suggest that they are "triggering"): "the trauma reappears, in effect, frequently unveiled" (ibid., 55). The reality principle is responsible for retaining this encounter with trauma by preserving some degree of pleasure for the subject: "let us conclude that the reality system, however far it is developed, leaves an essential part of what belongs to the real prisoner in the toils of the pleasure principle" (ibid., 55). Hence, we are not only subjects within the so-called prison-house of language but we are also prisoners of enjoyment and *jouissance*. Our encounter with *jouissance* imprisons us within impossibility. The reality principle – which, for Lacan, was really only a "delayed action pleasure principle," and thus an extension of *jouissance* folded back upon itself in self-preservation (therefore effectively withholding excitation) – effectively places the subject within traumatic impossibilities as a form or repetition which never ceases to not be properly symbolized within the system of human comprehension.

At this point we reach a problem. Although there are two levels of repetition – first there is the pathological repetition of the symptom or the manifestation of imaginary and symbolic unconscious material, second there is the circular repetition of the drives eluding symbolization – then *automaton* must be related to the former while *tuche* must be related to the latter. Whereas *automaton* is related to the symbolic unconscious, that is, to the latent and manifest dream-

work, there is also within the dream-work an undecipherable impossibility encountered as what Freud named the dream's "navel." Similarly, at some point during the work of analytic interpretation, there appears to be an unsurpassable "hard rock of castration anxiety": something completely eludes symbolization, absolutely. This radical kernel of nonsensical "stuff" punctures a hole in the signifying material, giving rise to a "hole in meaning." Yet this "hole" should also be understood as that which urgently gives rise to meaning. In other words, this "hole" also pushes the subject toward meaning as his only partial exit from the overwhelming world of *jouissance*.

We cannot do otherwise but experience this *tuche*, this encounter with *jouissance*, as "something missing" as a "missed encounter" (ibid., 54) since there is no symbolic or imaginary framework capable of absorbing it. The cause of any future or current possibilities is related to this primordial and fundamental impossibility of the "hole" such that necessity arises as a consequence of impossibility. Put differently, it is necessary that something stand in place of the traumatic *jouissance*, and it is necessary that the subject discover – whether through the introjection of a primary signifier or else through the invention of a sign or code – a substitute for the trauma. Thus, it is not only that our symptomatic pathologies are derived from unsymbolized or hitherto repressed determinations but rather that all of our pathologies are attempts also to cure ourselves of the traumatic hole. Those fixated on "impossible impossibilities" therefore attempt to bring into existence that which already anyway exists, and the "impossible possibilities" are merely the ongoing operations of the subject existing as a consequence of trauma. We might even claim that the subject is him or herself nothing but the object of this trauma. The real is a cause which therefore "does not stop not writing itself" since it endlessly preserves its place as a potential trauma within any signifying chain even while giving rise to that very chain (Lacan, XX: 50).

There was a point of connection to the final teaching of Lacan when, during his 19th seminar, he discussed a surface with the following

important vertices: necessity/existence, undecidability/impossibility, possibility/contradiction, and object/contingency. I cannot explore all of these vertices in detail, but I would like to comment upon one or two of them. First of all, each position is related to the speaking-being's place within discourse such that there is a struggle by each with the impossibility of there being any sexual relationship. Ultimately, the sexual relationship is the key site of impossibility. Yet, to be clear, it is not the impossibility of the relationship between one sex and the other – between the one and its excess or limitation – but rather the impossibility of one sex to fully and harmoniously account for itself. In this conception, impossibility/undecidability is related to the Lacanian statement on feminine sexuation that “there does not exist one who is not submitted to symbolic castration.” This statement serves as the counterpoint to the more popular one that “not all women are submitted to symbolic castration.” Does this not imply that the very concept of impossibility is tied essentially to femininity? The condition for any man to position himself within the impossible is to become feminized in some manner.

Is this not why love is one of the most important names we have for the linkage of realism with impossibility? Take, for example, Jacques-Alain Miller's statement “[any] dialogue from one sex to the other is impossible, as Lacan said with a sigh. People in love are in fact condemned to go on learning the other's language indefinitely, groping around, seeking out the keys – keys that are always revocable. Love is a labyrinth of misunderstandings whose way out doesn't exist” (Miller 2013). At the same time, we should be prepared to admit that is also the pleasure of love! Those in love situate themselves there within its impossible jouissance through feminization. Miller continued: “[love] is essentially feminine. One only really loves from a feminine position. Loving feminizes. That's why love is always a bit comical in a man” (ibid.). The formula of feminine sexuation begins with “there does not exist . . .” which indicates the radical externality of love's possibility since these are experiences that are not reducible to language or identity. We must be very careful in presuming that this secures for woman a

place outside of any homogenous identity, since, as Slavoj Žižek correctly argued, the fact that there does not exist a woman who is not subjected to castration implies all the more that woman is implicated in the quest to “try out” various identities (Žižek 2005). Put another way, inexistence only compels the subject all the more toward masquerade.

One the other hand, possibility is related to the masculine position (but only on the condition of its contradiction). The masculine statement of sexuation begins with “all men are implicated in symbolic castration,” that is, are walking contradictions. We might claim that possibility itself is determined by the impossible, which is why we position the latter in the space of the adjective and the former in the space of the noun: “impossible possibilities.” It is only through the logic of inexistence – the inexistence of the Other who is not subjected to castration – that impossibility as cause arises as the feminine basis through which trauma repeats itself. No wonder Lacan placed the impossible at center stage as that which sustains the possible. Indeed, the Lacanian discovery has no other meaning than this one. Jacques-Alain Miller, during the conference in Comandutaba, stated the following:

The Lacanian practice, if it is to be distinct from the others, can have no other principle than: “it fails.” The Lacanian practice, it fails. You will even recognize in this failing, a *leitmotif* of the later Lacan. He did everything to place himself in the position of failing his knots, and evidently, this failure is not a contingent one. This failure is a manifestation of an impossible. Moreover, Lacan was led to this by Freud's own indications, was he not? Psychoanalysis, the impossible profession. In effect, these notions of failure and of the impossible invaded us, his listeners and his readers. He inoculated us with these terms, precisely the terms that protect us, that have protected us, which have been like the antibodies to the discourse of “it works” and the new practices of psychoanalysis which have the latter as their principle. The Lacanian practice excludes the notion of success. (Miller 2004)

The impossible is simultaneously that trauma which must be eradicated through the signifier or the substitute code and yet it is also that which gives rise to the very possibility of possibility, and, as a consequence to the space of the impossibility itself.

Summary

This entry has traced three periods of development in the Lacanian notion of the impossible, finding that Lacanian psychoanalysis is not prepared to follow the revolutionary sentiment which insists that we must be realistic and demand the impossible. Lacanians are content only to find what within the impossible as cause gives rise to the necessity and possibility of speech.

The Possible in the Life and Work of Jerome Bruner

Giuseppina Marsico

University of Salerno, Fisciano, Italy

Federal University of Bahia, Salvador, Brazil

Abstract

One core element of Jerome Bruner's intellectual program is "the possible" as a crucial dimension of our psychological processes and a privileged locus to investigate the interconnection between culture and psyche. Bruner considers the undeniable value of the potential, of the hypothetical, and of what neither was nor perhaps will ever be, but which could have been. In this sense, the exploration of the realm of the possible is configured as the creation of alternative worlds that throw new light on the real world. Narrative is the way to foster our hypothetical thinking. Narrative thinking is strictly related to the imaginative function. A person organizes the world into narrative structures, exploring different possible interpretations of events. She locates experience into a spatial-temporal frame, looking for connections and justification, attributing intentions and motivation to the characters. Narrative structures become the sketch for the creative production of new scenarios. Cultivating the sense of what is possible in our cultural practices epitomizes the Brunerian constructivist vision of the human being as a future-oriented agent who strives to overcome the borders of actual reality toward new possible worlds.

Bruner · Culture · Possibilities · Narrative · Education

Introduction

For those who met Jerome S. Bruner sometime during his long life (1915–2016), they know how hard it is to talk of him as one of the giants of

contemporary psychology without talking of him as a man. In Jerome Bruner's trajectory, the professional and personal components are inextricably interwoven. Yet, there are some who talk of Jerome Bruner without having known him directly, and others reluctant to talk about him precisely because they knew him and know how revolutionary his presence was to ever-changing perspectives on the world and on human beings (Marsico 2015a, 2017). Jerome Bruner often started talking to the people around him by saying "Let me tell you a story." The following notes offer a narrative summary of Bruner's academic trajectory.

The Interconnection Between Psychology, Culture, and Education

During the Guest Lecture that Bruner gave at the University of Salerno (Italy) on June 29, 2011, he addressed the always intriguing theme of the relationship between psychology, culture, and education. The lecture's title recalled McLuhan's quip "I don't know who discovered water but it wasn't a fish!" which evokes the idea that we are like fish and the water is the set of our assumptions about the world, many of which are so present in our existence that we do not even see them. They become invisible to our gaze. Bruner was asked the question: "But did it happen that the fish discovered water?" In his rigorous, provocative, and elegant speech, he said that we are like fish in water: We are completely immersed in the culture, we breathe culture, and we realize how pervasive it is only when we step out of the sea in which we are swimming and explore other waters for a while. In this new position, we are able to see the cultural environment we grew up in from a new, external perspective.

Bruner, in fact, argues that all mental processes have a social origin and are influenced by culture through its symbols, its artifacts, and their contexts. To understand, therefore, how we become "human beings," we should take into account how individual action develops through participation in culture and the sharing of its symbolic systems. Bruner emphasizes the

formative role of culture as the main factor that shapes the mind. His approach to education is one of close interaction between education and the culture within which it operates. This requires particular attention to the resources that the context makes available through formal and informal educational processes.

Bruner observes that one enters into culture; one does not learn it (Bruner and Feldman 1993). After all, a person participates in a system of meanings that influences her to such an extent that the cultural dimension becomes a constituent element of her own identity. At the same time, the person, through his continuous interpretive intervention, will contribute to the constant remodulation of culture. The complexity and salience of the connection between psychology, culture, and education thus appear in all its evidence.

Cultivating Possibilities

One core element of Jerome Bruner's intellectual program is "the possible" as a crucial dimension of our psychological processes and a privileged locus to investigate the interconnection between culture and psyche. In particular, this interconnection highlights the undeniable value of the potential, of the hypothetical, and of what neither was nor perhaps will ever be, but which could have been. In this sense, the exploration of the realm of the possible is configured as the creation of alternative worlds that throw new light on the real world (Bruner 1986, 2003).

The exploration of human situations through what Bruner defines as the prism of the imagination is characterized as necessary to reexamine the obvious. In this sense, it becomes necessary for the construction of identity. The fantastic and imaginative component for Bruner not only correlates with fable, legend, and literature, but also shapes the real world. Bruner supports the great ability of myth and tale in its multiple guises to shape human experience. If life, on the one hand, nourishes literature through the possibilities that experience implies, literature, on the other hand, shapes experience and orients culture.

According to Bruner (1979), education to the use of narrative, to the intuitive thought and metaphor, should be the principal task of the teacher. In *On knowing: Essays for the left hand* (1979), Bruner outlines the existence of two modes of thinking: paradigmatic thought that verifies how things are and narrative thought that hypothesizes how they could be or might have been. Paradigmatic thought is conjugated in the indicative mood, due to its certain and defined identity; narrative thought, on the other hand, appears in the subjunctive mood of possibility and uncertainty. The alliance between the two is not only desirable, but also necessary.

School, despite the plurality and diversity with which it is confronted, usually chooses the linearity and safety of the indicative mode to the detriment of the uncertainty and complexity suggested by the subjunctive mode. Bruner (1979) refers to a particular form of combinatorial activity that takes its moves from *multiplicity*, defined as a productive surprise. The ability to understand the complexity and different perspectives within the self and in real life leads the observer/student to be struck by the unexpected, generating a surprising new possibility.

Specifically, Bruner identifies three forms of productivity. First, one form allows making a prediction via sudden intuition or slow process of maturation and collection of knowledge in the field of science. The second restores order to the elements, highlighting not immediately visible relationships and connections, as happens in the fields of music and logic-mathematics. The third form is a metaphorical one, in which the synthesis that connects disjointed aspects of experience pertains to the field of art. The metaphorical procedure explores unexpected connections when considered in relation to common experience, creating what we will call a new syntax of concepts. In this sense, each observer, each student, is called to mediate the experience through the symbol, so as to find the most useful combination.

School should educate the awareness that the ego is not the center of the world, that reality is anything but linear, and that the sense of things does not pass objectively and completely through the attributions of meaning and perspectives of the

individual. Reality is expressed between rational exactness (Bruner's "paradigmatic thinking") and frenetic deformation (for Bruner, "narrative thinking"). School must know how to welcome and manage this complexity, providing students with the means for productive surprise to look for a new syntax, for the possible.

In the classroom, the teacher can elaborate the different antinomies within the creative activity of the multiple:

- By moving away from everything that may seem obvious. He moves away from the usual forms of reality to educate in the formulation of new and different interpretations.
- By managing passion, which grows when trained and which always works in dialectic with decorum, as the impulse always requires a certain amount of reflection (Bruner 1979).

In *Making stories: Law, literature, life*, Bruner describes this multiplicity as what comes after the story (Bruner 2003), that is, not the answer, the solution, the perspective that the story brings in, but rather the problem, the question, the reflection that it arouses and nourishes. The multiplicity described by Bruner is not only intended as an infinite network beyond the story – it has its own dimension in the person, in the centrifugal force that moves her, keeps her alive, and makes her mortal and fleeting.

Here is the process through which the experience is declined in the subjunctive tense. This is what Bruner means when he argues for the need to transform the indicative into the subjunctive. Rooted in what appears familiar (1990), the narrative re-elaborates what is felt as canonical and what manifests itself as possible. The dialectic between the two apparently distant elements is realized in the story which aims to keep the past and the possible acceptably united (Bruner 2003). Bruner's narrative refers to enacted possibilities. Narrating, indeed, not only has to do with memories of the past but also is a symbolic enactment of the present and, even more interestingly, a way to imagine, hypothetical events and possible worlds. People sometimes narrate possibilities they achieved in the past, but narrating is also a

means for imagining what has never occurred and what will never occur. Narrative is a medium at once rooted in reality but also employing symbolic devices. Narrative is the way to foster our hypothetical thinking. Narrative thinking (Bruner 1986) is strictly related to the imaginative function (Tateo 2020).

The person organizes the world into narrative structures exploring different possible interpretations of the events. She locates experience in a spatial-temporal frame, looking for connections and justification, attributing intentions and motivation to the characters (Bruner 1986). Narrative structures become the basis for the inner dramatization and the creative production of new scenarios. Although narrative thinking and imaginative work are universal, narrative structures and frames are, of course, framed by the cultural repertoire of symbolic forms, values, and contexts of activity. We all grow up immersed in a web of bedtime stories, religious myths, cartoons, fairy tales, and short stories drawn from advertising (Pascarella et al. 2021). Additionally, Bruner writes that the creation of the Self is a narrative art. Speaking of the self, thus, becomes synonymous to speaking of the many selves made up of memory, feelings, ideas, beliefs, and subjectivity. However, the creation of the self draws a great deal from cultural guidance (Valsiner et al. 2016), from the expectations of others, and from the culture in which we are immersed and in which we have been formed:

Identity is situational and is distributed among all those groups, institutions and individuals that make up the texture of our lives. In constructing the feeling of being ourselves, of who we are, we use narrative that has a component of fiction, of storytelling. We go along building and evoking fictitious identities that enable us to give meaning and coherence to our lives, to cope with what happens to us and to explain things that break the canonical or established models. (Bruner 2005, p. 14)

The cultural model, tacit and implicit and yet so striking, transforms identity into *res publica* (Bruner 2003) and to put in the subjunctive way *the experience* to the extent that it confronts the person with the otherness that is, by its nature, multiple and composite. In the always rich and

confusing realm of human interactions, we create a lifeworld inhabited by narrated stories (Bruner 1986, 1990, 1991, 2003) in the form of narratives, such as histories, stories, myths, and ideologies. For Bruner, narrative seems as natural as language itself. Narrative, in fact, is a conventional resource for the creation and transmission of the culture. Narrative does not call for any truth/falsehood verification. It need only satisfy the criterion of “verisimilitude,” which appeals to the coherence of our experience, the need to communicate a specific knowledge of the world and to understand ourselves and others. According to Bruner:

Insofar as we account for our own actions and for the human events that occur around us, principally in terms of narrative, story, drama, it is conceivable that our sensitivity to narrative provides the major link between our own sense of self and our sense of others in the social world around us. The common coin may be provided by the forms of narrative that the culture offers us. (Bruner 1986, p. 69)

In other words, the study of narratives is not just an investigation of narrated fact, but of how we make worlds (Goodman 1975) and how we make ourselves and how we foresee new future possibilities (Bruner 2001).

Conclusion

Over the course of his career, Bruner covered a number of different fields to which he always made original contributions. Yet, in Jerry’s inquisitive mind, from the very beginning there had been three main questions: “*What makes human beings human? How did they get to be that way? How can you be more so?*” This is the very core of cultural psychology! The fundamental issues of who we are as humans and how we become humans imply a holistic approach to the *psyche* in its complexity (Valsiner 2014). The legacy of Jerry Bruner is taken over by those scholars that are working in turning psychology into a science of the human ways of being. Being is not merely an ontological state, but the *process of existing* that entails the construction of the human world (Valsiner et al. 2016). Cultural

psychology, thus, is the science of *human* nature and of specifically human ways of existence that starts from the perspective of higher psychological functions to look at how their lower counterparts are reorganized. Cultural psychology “cultivates new possibilities” for studying behavior or cognition by looking at the normativity and narrative dialogicality of higher psychological functions in multiple forms and arenas of human activity.

The human psyche is goal-oriented, operates on the borders between past and future, and unites personal and social sides of its development through various aspects of culture. As Bruner pointed out in his last interview before his death (Marsico 2015b), psychology necessarily deals with conflicting, unpredictable, and ambiguous situations. Thus, human dilemmas are, heuristically speaking, the most fitting phenomena to investigate. These dilemmas challenge the culturally established set of meanings, making the emergence of novelty possible. The borders between *actual* and *possible worlds* are at stake here and acquire an epistemological and methodological relevance in our globalizing societies, where the social practices of border construction and reconstruction (Marsico 2015b) and the cultural organization of borders within educational settings (Marsico et al. 2015) have profound implications on how we can *become more human*, cultivating new developing possibilities for the next generations. In Bruner’s own words:

I want psychology to enter the world more fully, as Malinowski did nearly a century ago, in his brilliant *Crime and Custom in Savage Society*. I think such cultural inquiry (which is growing) is essential for cultivating and maintaining psychology’s breadth and scope. They make us forever aware of the constraints and the opportunities that characterize the human condition. (Bruner 2012, p. 12)

Once again, Bruner’s ideas are feeding the advancement of contemporary cultural psychology (Bruner 1996; Tateo 2016). Cultivating the sense of what is possible in our cultural practices epitomizes the Brunerian constructivist vision of the human being as a future-oriented agent who strives to overcome the borders of actual reality toward new possible worlds.

The Possible in the Life and Work of John Dewey

Kjetil Egelanddal and Ingunn Johanne Ness
Centre for the Science of Learning & Technology
(SLATE), University of Bergen, Bergen, Norway

Abstract

The American philosopher John Dewey and the tradition of pragmatism is often connected to the concept of experience. This entry explores John Dewey's pragmatism with a particular emphasis on experience as transformative events based on two main principles – continuity and interaction. In relation to this we discuss how experience is linked to imagination and seen as a transformative source. Experience can be perceived as a creative process in which the meeting of different experiences creates new ideas and new understandings revealing what is possible. Consequently, experiences do not only form the basis for what we can do and understand, but also what we can imagine and create. Despite the positive and educative associations to the concept, experience is not always an educative phenomenon and Dewey realized that some experiences can also be harmful. Thus, in order to understand the complexity of the concept we also elaborate on educative and miseducative experiences, and the relationship between experience and moral judgement.

Keywords

Pragmatism · Dewey · The possible · Experience · Imagination

Introduction

In this chapter, we will focus on how we, through our interaction with our environment, undergo experiences and change through these experiences. The focus is especially directed on how our experience opens the possibilities for what we can learn, think, and understand, how we see ourselves and the world, what we can imagine, and how we act. This is done in light of the philosophical tradition of pragmatism and the American philosopher and educator John Dewey.

We start by presenting the pragmatist view of knowledge and Dewey's conception of experience as transformative events that are based on two principles: the principle of continuity and the principle of interaction. Further on, we discuss Dewey's concept of experience in relation to imagination and the possible, before moving into experiences as educative and miseducative, and finally, their relation with interpretation and moral judgment.

Pragmatism

Pragmatism is a philosophical tradition that originated in the USA around 1870. Charles Sanders Peirce (1839–1914), William James (1842–1910), and John Dewey (1859–1952) are considered the most central pragmatists. In recent times, philosophers like Richard Rorty, Hilary Putnam, and Robert Brandom are also regarded as representatives of this tradition.

The term pragmatism comes from the Greek word “pragma,” which means action or practice, and what characterizes pragmatism is precisely the emphasis on practice and humans as acting beings. This emphasis on action is associated with the idea that the consequences of our actions determine whether an idea or practice is acceptable or must be rejected. From a pragmatic point of view, for example, it is reasonable to claim that knowledge and ideas are best understood considering their practical uses and functionality. In this lies the fact that “truth” is closely connected with our experiences of “what works.” This is why Dewey (2008 [1938]) uses the term “warranted

assertions” when talking about knowledge. The reason for this is that we can potentially always make new experiences that challenge what we already know. In other words, it is when our ideas and knowledge are tested and we experience their consequences that we realize whether and if they are usable or must be rejected or revised. It is important to note that even when an assertion is confirmed, it remains a “warranted assertion.” This implies an openness to the fallacy of what we believe is true. This is why pragmatists often argue that the goal of research is to be useful (James 2000; Johnson and Onwuegbuzie 2004; Noddings 2007; Feilzer 2009). From such a perspective, the value of knowledge is assessed through its use, i.e., knowledge is primarily a tool for exploration and practice that needs to be tested.

John Dewey

John Dewey (1859–1952) was born in 1859 in Vermont, USA, the same year as Charles Darwin’s *The origins of Species* were published, and Dewey’s philosophy is clearly inspired by these naturalistic currents. However, this is not reductionistic naturalism attempting to explain the human condition through narrow scientific methods and concepts, but a naturalism that considers humans as agents who interprets and acts in their environment through their experiences, intentions, and values.

When reading Dewey, we soon realize that experience is a key concept, which is highlighted in the titles of his works: *Experience and nature* (1921), *Art as experience* (1934), and *Experience and education* (1938). With his concept of experience, Dewey presents a nondualistic understanding of reality that rejects traditional distinctions between theory and practice, thinking and action, facts and values, etc. Instead, he considers human thoughts as “tools” for expectations, problem-solving, and action, and rejects the idea that the function of thoughts is to describe, represent, or mirror an immutable reality. For Dewey, our thoughts and ideas are inevitably used in our actions, and our experiences of

the consequences of when we act change our ideas based on how they work. In this way one can say that the human condition is to be in a continuous interaction process with the environment around us – where both our understanding and the environment change in light of what we experience.

Experiences as Historically Conditioned and Transformative Events

Dewey (1997 [1938]) considers experiences as transformative events that change those who undergo them as well as their ability to make new interpretations. The concept of experience is therefore related to the phenomenon of understanding and this affects how new insights, attitudes, and moral judgment are formed. Experience is according to Dewey (1997 [1938]) based on two principles: *the principle of continuity* and *the principle of interaction*. We will first look at the principle of continuity. This entails that process of experience always connects the present and the past because past experiences affect how future experiences become. The other principle, the principle of interaction, is about new experiences arising through the interaction between the individual’s internal conditions (shaped by previous experiences) and external (“objective”) conditions (consisting of the environment surrounding the individual):

... it [the principle of interaction] assigns equal rights to both factors in experience – objective and internal conditions. Any normal experience is an interplay of these two sets of conditions. Taken together, or in their interaction, they form what we call a situation. (Dewey 1997 [1938], p. 42)

In other words, through this interaction, new experiences are made possible, but also limited by the conditions who are present (both internal and external) in each situation. Because a person’s internal conditions are shaped by previous experiences, previous experiences are crucial for how external conditions are interpreted and how a situation is formed. The principle of continuity and the principle of interaction are, thus, inextricably connected:

What he [the individual] has learned in the way of knowledge and skill in one situation becomes an instrument of understanding and dealing effectively with the situations which follow. The process goes on as long as life and learning continue. (Dewey 1997 [1938], p. 44)

This means that we use our previous experiences when interpreting a new situation; at the same time, our new experience of this situation changes our understanding and shape how we interpret future situations.

In order to understand these abstract notions, let us imagine a machinist facing a broken car engine. Although he/she only has experience in repairing boat engines, he/she will still have better prerequisites for repairing the car engine than a teacher or a doctor. Nevertheless, he/she might experience that his/her knowledge is not sufficient to repair the given engine, and that he/she needs to make new experiences that can provide him/her with better insights. One can imagine that he/she thus initiates a thorough investigation in which he/she searches for information on the Web (discussion forums, manuals, etc.), studies the engine carefully and tests various solutions, and maybe contacts a friend who is a car mechanic. The experiences the machinist undergoes through these interactions changes his/her understanding of the specific car engine and engines in general. These experiences can, thus, be used to both to repair the car engine in question and to interpret and act in new situations in the future.

It is, however, important to note that this process of experience is not just a linear process that cumulatively helps us understand the world better and act in it, it is also very much a creative process in which the meeting of different experiences creates new ideas and new understandings of what is possible. Experiences do not only form the basis for what we do can do and understand, but also what we can imagine and create.

Experience and Imagination

To Dewey, imagination is an integral part of human activity, experience, and growth (Krüger 2002, p. 188). Imagination serves as stimuli for

thinking and reflection and can be said to be a transformative force of the mind that is connected to the possible and enables us to grasp what lies beyond what we can observe. Dewey sees imagination as a natural part of learning and communication that extends beyond the situation we are in here and now. Dewey points to how a child can play with a boat and imagine other situations with the boat, as an example of how this ability drives the child's activity forward. He says that the child can:

... change the material that serves as a boat almost at will, and introduce new factors as fancy suggest. The imagination makes what it will of chairs, blocks, leaves, chips, if they serve the purpose of carrying the activity forward. (Dewey 2004 [1916], p. 165)

This quote shows how a child is able to consciously recreate images in the mind based on experiences with events or objects, and then use these experiences to imagine something else. This quality is also central to our empathy and capacity to understand other human beings as well as our ability to solve different problems.

Problem-solving is very much an act of reflection. Dewey sees problem-solving as a process developing in five stages: First, we have a perceived problem, disagreement, or conflict arising. Second, we think through the problem and try to find out what is essential in order to solve it. Third, we try to imagine different possible solutions. Fourth, we start developing hypotheses through reasoning and experimentation. Fifth, we observe and test and this results in the approval or rejection of our hypothesis. Dewey (2004 [1916]) argued that it is crucial to gather information that makes it possible to investigate the problem at hand in an appropriate way and that it is important to actually test out the hypothesis to see if they hold. In any case, the problem-solving process will be something one can explore and learn from.

Dewey does, however, not consider problem-solving as an individual activity, but more as a social process in which people are jointly trying to solve problems. In such processes in which new ideas are to be created and tested, imagination plays an important part. What an individual possesses as knowledge accumulated through its past

experience serves as a tool for what it can understand and can imagine. In short, an individual's past experiences form a repertoire of tools that informs a person's mind and will influence the options that seem possible for that person in any new situation. In daily life, when a group of people discuss how to solve a problem together, a potential exchange of experience will often take place. Most likely they will have different experiences and this diversity is key to stimulating the imagination when they share their different views (Ness 2020). It is, however, important that the participants of a discussion manage to share their ideas in a way that becomes meaningful for each other to establish a common understanding. Furthermore, for new ideas to be imagined, it is also important that the different perspectives challenge each other. In this way, the individual's imagination can be expanded through a reconstruction of previous experiences, making new solutions appear. It is worth noting here that this is the same process as the processes enabling new knowledge and technology to emerge and be developed in a culture.

In the next section we will explore this further and look at what conditions must be present for a new experience to take place.

Conditions for New Experiences

So far, we have seen that according to Dewey (1997 [1938]) we are continuously engaged in an interactive process with our environment. Through this interaction, new interpretations become possible, but also limited by the conditions present (both internal and external) in each situation. The current situation, however, both relates to the future and the past. The future because we engage with our environment through our plans and expectations. The past because our current understanding is formed by previous experiences which condition how new situations occur for us. The process of experiencing is, thus, continuous, where the interplay between past experiences, plans for the future, and external conditions affect how new experiences come into being. This continuity of experience can

therefore be depicted as a spiral. Since every spiral of experience is unique, since no one lives identical lives, our expectations, interpretations, and understandings will be different.

This way of thinking about experience is very similar to that of the philosophical hermeneutics, represented by the German philosopher Hans-Georg Gadamer. According to Gadamer (2012, p. 347), we can consider two types of experiences: experiences that correspond with our expectations and confirm them, and new experiences that thwarts our expectations. Gadamer regards the latter as real experiences, experiences which are essentially negative because they disprove our expectations. This negativity is, however, a productive one because it liberates us from wrongful assumptions and provides us with new insights. That is, a new experience implies, on the one hand, acknowledging that one's understanding was inadequate, while, at the other hand, it entails acquiring a new horizon of understanding shedding new light on a matter (Gadamer 2012).

Gadamer (2012) also highlights the linguistic dimension in an experience. Experiences are not only a consequence of pure sensory impressions, but the result the dialectical interaction between questions and answers, between the interpreter and what is interpreted. When we interpret something, we use our preconceptions (prejudices) as an interpretive framework. That means, the questions we can ask are made possible, but also limited by our horizon of understanding. In other words, our previous experiences represent the opportunities for the dialogues we can have with the world, making certain conversations possible and others impossible.

According to both Gadamer and Dewey experiences are not just a matter of new insights in a particular area, but something that changes our understanding holistically. An experience represents a breach with our expectations that allow us to see ourselves and the world in a new perspective. That is, the experiences we undergo affect how we become as human beings.

To illustrate: When reading a text, you use relevant past experiences to ask questions to the text and interpret its meaning. Through this process of interpretation, you might be subjected to

unfamiliar perspectives that changes your horizon of understanding and the questions you are able to ask. This affects both the way you understand the text itself and your ability to interpret other texts in the future. Such an experience, however, is not solely restricted to text interpretation, but also provides a new horizon of understanding through which you can see yourself and the world.

In our lives these interactions happen continuously through our meetings with other human beings and the materials that surrounds us, where both the internal and external conditions in our environment affect our interpretations and how our horizon of understanding changes. Because we all live different lives, our understanding and imagination will differ.

It is, however, not so that all changes are for the better. Dewey (1997 [1938]) argues that in the context of educating and parenting, we need to separate between experiences that are educative, miseducative, and noneducative.

Educative, Miseducative, and Noneducative Experiences

Dewey (1997 [1938]) distinguishes between experiences that are noneducative, educative, and miseducative. Noneducative experiences refer to interactions between the individual and its environment that do not contribute to new experiences; for instance, if the individual does not get a meaningful experience out of a situation because there is no connection between previous experiences and the object of interpretation. For example, you cannot read a text in Japanese if you do not understand the language. An attempt to read the text will thus become noneducative, at least in terms of understanding the text. Similarly, a situation might be noneducative if it simply confirms what has already been experienced before. For example, you might observe that throwing a rock into the air results in the rock coming down again, as you have experienced before. Hence, no new experience is made.

Dewey (1997 [1938]) realizes, however, that the question of experience is not simply a question about gaining new experiences regardless of their

consequences. It is also a normative question, at least from the perspective of an educator or parent who needs to consider that some experiences might also be harmful for their children/pupils. Dewey therefore separates between educative and miseducative experiences in terms of what an experience may lead to. Using “growth” as a metaphor, Dewey (1997 [1938]) associates growth with the ability to make new experiences in new directions. The quality of an experience is, thus, related to whether it promotes or restricts the opportunity for future experiences. According to Dewey (1997 [1938]), an experience that offers good conditions for growth in new directions is considered educative, while an experience that inhibits or disrupts growth is considered miseducative.

Although all experiences both promote and inhibit opportunities for further experiences, one can imagine that some experiences are less restrictive than others. For example, learning to read will probably open a child to many new experiences. While, conversely, experiencing that others do not value you may be restrictive for your possibilities to make social experiences. Furthermore, it is important to note that it is not only the external conditions themselves that determine whether an experience is educative, but how the external and internal conditions interact. Therefore, the same external conditions can lead to different experiences depending on an individual’s internal conditions. This means that even the process of learning something commonly considered good may have undesired consequences. Dewey calls this “collateral learning”:

Perhaps the greatest of all pedagogical fallacies is the notion that a person learns only the particular things he is studying at the time. Collateral learning in the way of formation of enduring attitudes, of likes and dislikes, may be and often is much more important than the spelling lesson or lesson in geography or history that is learned. For these attitudes are fundamentally what count in the future. (Dewey 1997 [1938], p. 48)

The point is that the experiences a person makes help to shape how he/she becomes. In other words, an experience means not only that we understand an object, phenomena, etc., in a certain way, but also that we understand ourselves

in a certain way through the experience as a whole. In this way, any experience becomes a point of reference for how we understand ourselves in the world. A parent or a teacher can therefore not be content with focusing exclusively on external conditions of the child(ren) which he/she is responsible for, he/she must also take into account their subjectivity and development as human beings. In the next section, we will look at how the process of experience is also connected with the development of moral judgment.

Experience and Moral Judgment

Educative experiences for Dewey (1997 [1938]) imply a gradual emancipation from immediate impulses and drives. Since we, as human beings, can plan the future in the light of past experiences, we are not bound by a particular situation in time, but able to take a general perspective independent of our immediate desires. To take a general perspective is not solely an innate ability, but a result of experience and linguistic development. Our ability to anticipate and assess the consequences of our actions and inactions are therefore shaped through the life we live.

However, anticipating and assessing the consequences of an action also means making an ethical assessment. At this point, Dewey's concept of experience is similar to the ancient philosopher Aristotle's (2009) concept of moral judgment, *phronesis*. *Phronesis* differs from fixed skills and knowledge in that it is about judging what may in principle be different. While skills and knowledge make it possible for a person to change tires on a car, *phronesis* concerns judgment of when one *should* change the tires. This kind of contemplation relates to our actions, that is, to consider what is the right thing to do in each situation. In other words, it is this reasoning we use in daily life when we decide what we do and what we refrain from doing. This ability to make moral judgements is related to our experience, understanding, and imagination as a whole.

When we experience something unfamiliar in a specific situation, this experience changes us and

leads to new understanding and self-understanding. This affects how we interpret new situations. Our experiences, however, also affect our attitude to what is right and wrong, and our ability to judge what is right in the individual situation. We therefore use our imagination and judgment, shaped by past experiences, when we consider what a specific situation requires from us. Our understanding and judgment are, in turn, affected by how we experience the consequences of our actions. In other words, experience, understanding, imagination, and judgment are intimately related:

1. We interpret a new situation through our current horizon of understanding.
2. Through our understanding of what the situation requires and imagining possible solutions we act.
3. The experiences we undergo as a consequence of our actions affect our understanding and self-understanding we change.
4. We can face new situations with changed imagination and moral judgment.

Knowledge and skills are tools we use when we act, but these tools can be used differently depending on how a person interprets a situation and what this person might want to achieve. An action is thus a result of what we can understand, what we can imagine as possible, and what we can do. What we *can* do is, however, subordinate to what we *choose* to do. Our imagination, skills, and knowledge must therefore be considered in the context of our moral attitude to what is right and wrong. Dewey (1983 [1922], p. 194) argues that it is wrong to make moral "A separate department of life." According to Dewey, morality is not something that we only use on special occasions, all situations require moral judgment. This is as much about assessing what one should refrain from doing, as what one should do. Of course, a person's moral judgment may be more or less morally conscious, and actions may be considered more or less morally sound. The point is that all situations place moral demands on the individual. How we chose to interpret and react to these demands, however, will differ from person to person. In

retrospect, many of us probably think that we have sometimes acted right and sometimes acted wrong. What we should have done, we often do not realize until later. Such experiences, however, can help us assess and imagine future situations.

Conclusion

In this chapter we started by presenting the pragmatism's view of knowledge and Dewey's conception of experience as transformative events that are based on two principles: the principle of continuity and the principle of interaction. Further on, we discussed Dewey's concept of experience in relation to imagination and the possible before moving on to experiences as educative, miseducative, and noneducative, and, finally, the relationship between experience and moral judgment. Through this presentation we have highlighted that experiences are considered by Dewey as historically conditioned transformative events occurring through a continuous and lifelong interaction process between individuals and their environment. They are historically conditioned because previous experiences affect how we interpret and deal with future events. They are transformative because new situations, in which new experiences are made, changes our understanding, providing us with new horizons through which we can interpret, imagine, and create. This implies a continuity where previous experiences are used in new situations, and new situations reconstruct our experiences. Knowledge and skills are tools we use when we act but these tools can be used in differently depending on how a person interprets a situation and what this person might want to achieve. An action is thus a result of what we can understand, what we can anticipate, what we can imagine as possible, and, thus, what we can do in the end. The concept of experience is related to the possible and to what we can imagine as a transformative source. Experiences do not only form the basis for what we do can do and understand, but also what we can imagine and create.

The process of experience can therefore be described as a spiral; an individual's horizon of understanding affect what experiences can be

made and how they are made, and new experiences affect the individual's horizon of understanding. Experience, however, is not only about acquiring new knowledge, but also about how one is formed as a human being, and is thus also a moral phenomenon. Experiences entail a real change of an individual understanding and self-understanding which reflects on one's moral judgment when imagining and choosing how to act in each situation. We are therefore at the mercy of our experiences in how we become as human beings. This requires a particular awareness from educators and parents to consider whether the experiences their children undergo are educative or miseducative in a broad sense.

The Possible in the Life and Work of Julia Kristeva

Nicoletta Isar

University of Copenhagen, Copenhagen,
Denmark

Abstract

A mode to address “the possible” in Julia Kristeva’s work is from the perspective of her concept *chora*, inspired by Plato’s similar term from his dialogue *Timaeus*. It is important to stress first the open character of Kristeva’s semiotic *chora*, and of the choral phenomena that take place in the semiotic *chora* in the process of the definition of the subject. Kristeva’s signifying subject is never fixed, but always in process, or in trail. Always in conflict with the symbolic function, and in revolt against prohibitions, the subject constantly searches for new possibilities of expression. The affective and conflictual phenomena, such as sensation, mood, and memory, situation and accident exceed the law of signification and determination of the subject in process. Kristeva’s *chora* makes room for the undetermined and undeterminable possible, challenging determination, fixity or stasis, and giving an insight into the extralinguistic processes, into the origins. In the absence of the semiotic *chora*, the humanities would remain “archivistic, archaeological, and necrophiliac” (Kristeva, RPL 1974, p. 13). The semiotic makes possible to express the unquantifiable processes, like poetic language, and the ephemeral arts that would never be inscribed in the process of signification. Kristeva’s view of art as the only means by which *jouissance* (pleasure) can infiltrate the symbolic order opens up to unexpected possibilities for signifying (poetic) subject. It gives poetry incomparable powers of expression. Creation emerges as a process of transformation of the semiotic into the symbolic, always a process of becoming, in which the possible manifests itself.

The semiotic *chora* · *sujet en procès* · Poetic revolution · Possible at last

Julia Kristeva: General Presentation

Julia Kristeva is a French psychoanalyst and philosopher, a literary critic and a novelist, as well as a practicing psychoanalyst. She was born in 1941 and educated in Bulgaria, being acquainted with the French culture, and the literature of Voltaire, Victor Hugo, Blanchot, Celine, as well as the Russian formalism and post-formalist theories, including Mikhail Bakhtin whom she introduced to French scholarship. She emigrated to Paris in 1965 to pursue her studies, after receiving an academic degree from the University of Sofia. In Paris, she has been introduced to the intellectual circle of French structuralism, Marxism, and Freudianism, and she attended seminars by Goldmann, Roland Barthes, and Jacques Lacan and Claude Lévi-Strauss. Kristeva joined the faculty of the University of Paris VII–Denis Diderot in 1974, and she received in 1979 the license for practicing psychoanalyst. Kristeva is the author of more than 30 books, and she is presently a professor emeritus at University of Paris Diderot–Paris 7.

The Psychoanalytical Work: The Subject in Process, and The Semiotic *chora*

In her first books, *Séméiotiké: Recherches pour une sémanalyse* (1969), *Le Texte du roman* (1970), and *La Révolution du langage poétique* (1974) (*Revolution in Poetic Language*, 1984) (RPL), Kristeva has already opened up a new direction of research in semiotics and linguistics. Her main theme of research was the speaking subject, around which she elaborated such concepts, as the abjection, love, and melancholia. These concepts are presented in the seminal books *Pouvoirs de l'horreur: essai sur l'abjection* (*Powers of Horror: An Essay on Abjection*, 1980), *Histoires d'amour* (1983) (*Tales of Love*, 1993),

Soleil noir (1987) (*Black Sun*, 1989), *Étrangers à nous-même* (1988) (*Strangers to Ourselves*, 1991), and *Les Nouvelles Maladies de l'âme* (1993) (*New Maladies of the Soul*, 1995).

Kristeva challenged the structuralism practiced in various fields, like linguistics, by Roland Barthes, Ferdinand de Saussure and Charles S. Peirce, anthropology and social and human sciences, by Lévi-Strauss and Althusser, as well as, Lacan in psychoanalysis. In her opinion, structuralism lacked dynamicity, operating with static structures, and the philosophical ideas practiced by structuralism were “nothing more than the thoughts of archivists, archaeologists, and necrophiliacs” (Kristeva 1974, RPL, p. 13). Kristeva sets herself the task to put forward a dynamic “theory of signification” that would allow changes and alterations, transformations, and open up new possibilities to work with the speaking subject within the theories of language. An illustrative example in this sense, developed in her book RPL, 1974 is the concept of the speaking being that she defines as a dynamic *sujet en procès*, that is, a subject in process or on trial. According to Kristeva, in the signifying process of language, the semiotic and the symbolic are two inseparable modalities since the subject is always both semiotic and symbolic. The psychoanalytic *sujet en procès* (subject in process/in trial) is a subject continuously in process/on trial between the semiotic and symbolic. Kristeva borrows the term *chora* from Plato’s dialogue *Timaeus* “to denote (48e-53c, 1975) an essentially mobile and extremely provisional articulation constituted by [bioenergetic] movements and their ephemeral stases” (Kristeva, RPL 1974, p. 25). For Plato, *chora* is a third genre of reality that exists before the generation of the cosmos, it is the space-in-between the visible cosmos (the copy) and the invisible/intelligible model. *Chora* is the matrix in which the universe comes to being, the world of Becoming, separated from Being. Plato’s *chora* is “a mobile receptacle of mixing, of contradiction and movement, vital to nature’s functioning before the teleological intervention of God, and corresponding to the mother [...]” (Kristeva 1977, p. 57). Kristeva defines the semiotic *chora* as the maternal receptacle or womb, “a place of chaos and which is and which becomes,

thus, without identity and without reason” (Kristeva 1977, p. 57). The chaotic space of *chora* “is and becomes a precondition for creating the first measurable bodies” (Kristeva 1977, p. 57). The semiotic *chora* “operates according to a maternal logic, which prefigures the Law of the Father. This law before the Law is the law of the mother’s body which regulates the oral and anal drives” (Kristeva 1974, RPL, p. 27), and provides the organizing principle of the maternal body, the “law before Law.” For Kristeva, the semiotic *chora* “precedes evidence, verisimilitude, spatiality, and temporality” (Kristeva 1974, RPL, p. 26), it precedes the ego thinking, this is to say, it exists before meaning exists (Kristeva 1974, RPL, p. 36). *Chora* is the necessary ground, essential to the functioning of sign and signification. Its function is to displace the speaking subject, tracing it back before *logos*, to the archaic preverbal maternal body. This displacement of the speaking subject generates a crisis in signification. The *chora* is the site of this crisis, but it is also a space where a new modality of signification operates. *Chora* is “a non-expressive totality formed by the drives (*pulsions* and their *stases* in a motility” (Kristeva 1974, RPL, p. 25), moving through the body of the subject, “always already in a semiotic process” (Kristeva 1974, RPL, p. 36). But it is this “multiplicity of expulsions” that ensures the “infinite renewal” of the subject, the infinite possibilities for its signification (Kristeva 1998, 134). This is what defines the subject in process, and the semiotic *chora* is itself the place of its perpetual renewal due to an infinite chain of body movements in the signifying process. Neither sign nor signifier, neither model nor copy, *chora* is a *process*, a verb not a noun, an operation analogous to vocal or kinetic rhythm, constantly to be restored (Kristeva 1974, RPL, p. 26). The “drives” are ambiguous, simultaneously assimilating and destructive (Kristeva 1974, RPL, pp. 27–28), and this movement belongs to the representation of *chora* as semiotic. Kristeva is indebted at this point to Freudian and Lacanian notions of the unconscious, the drives and primary processes that articulate the fragmented substance, not yet constituted as the body of the subject (Kristeva 1974, RPL, p. 25). This particular aspect is further discussed by Kristeva in terms of abjection in order

to define the chaotic, unformed maternal womb, which gives rise to language, and provides a place for that which is not itself linguistic. The bodily drives “extract the body from its homogeneous shell and turn it into a space linked to the outside” (Kristeva 1998, p. 143). By placing movement at the core of its structure, the semiotic *chora* presents an infinite potential and possibilities for creating signifying changes, and for transformations of the subject, threatening the unitary subject discovered by psychoanalysis by this movement, which is only one moment, a time of arrest, a stasis (Kristeva 1998, p. 134).

The process of signification takes place through two modes: the semiotic and the symbolic. According to Kristeva, semiotic activity is the work of the drives that stem from a semiotic body (Kristeva, *Desire in Language*, p. 136). The semiotic is rooted in the affective drives and energy, whereas the symbolic is the realm of language, of law and prohibition, which imposes order on experience. The semiotic mode manifests through rhythm, gesture, tonality, and affect, while the symbolic defines the subject through representations, signs, symbols, and meaning. In the process of signification, *chora* is the space of instability and duplicity, uncertainty and hesitation. The dualism of *chora*, which Kristeva represents as a tetrad or a double helix, makes the “semiotized body” a place of “permanent scission” (Kristeva 1987, *Soleil Noir*, p. 148), always at risk and unstable. Yet only together, the semiotic and the symbolic give signification to the subject, both through gestures and voice, as well as through articulated speech and words that carry the meaning.

The Semiotic *chora*: A Space of the Possible

In Kristeva’s theory of the subject in process, the semiotic is a medial space, as the Platonic *chora* is the third kind of reality, a space-in-between. Kristeva’s semiotic *chora* is the place that mediates between the imaginal and the rational, between the body and the mind, and between the self and the other. Finally, Kristeva’s *chora* is “a mediating space that preserves the alterity of the

entities engaged in the process of mediation, though not at the expense of their connectedness” (Margaroni 2005, “The Lost Foundation,” p. 82). This is a place of mediation, as well as a place of scission, a place of subversion of the symbolic logocentric masculine. It is thus a place of violence. The violence of the originary *chora* breaks the walls of the symbolic order and dissolves the logical order. As a result, “the subject crosses the border of the symbolic and reaches the semiotic ... which is on the other side of the social frontier” (Kristeva 1974, RPL, p. 79). The semiotic articulates a continuum among one’s drives, one’s vocalizations, and the symbols of one’s society (Kristeva 1974, RPL, p. 28). Entering into the semiotic area, one enters into the imaginal field, which disrupts the institutional frame of the self. The heterogeneous semiotic aspects of the self cannot fix its identity. Manifested in the “first echoaliases of infants” as rhythms and intonations, they predate the linguistic units of the psychotic language. This heterogeneity of the semiotic produces effects of poetic language, “musical” and “nonsense effects,” which destroy the settled rules and significations (Kristeva 1980a, “From One Identity to an Other,” p. 133). It shows the role of the somatic (the physical body) in the articulation of the imaginal, of language and, and the self. Referential for the discussions on the speaking subject are Kristeva’s texts of the 1980s, especially *Pouvoirs de l’horreur: essai sur l’abjection* (*Powers of Horror: An Essay on Abjection*, 1982).

In *Powers of Horror: An Essay on Abjection* (1982), Kristeva elaborates on the abject, unformed maternal womb, which arises in the passage from the semiotic to the symbolic in the development of the speaking subject. The process of signification is a process in constant making and unmaking, since the two modalities taking part in the definition are always in tension and contradiction. Meaning is disrupted, because the semiotic elements can disrupt the symbolic elements, and the unconscious can disrupt conscious meaning. As a result, a series of possibilities may open to create new configurations of the speaking subject, turning it into the “ground” for potentially infinite transformations of the subject. In this sense, we can say that the semiotic *chora* is the

place of all possibilities. This chain of possibilities, albeit, is a problematic “possible.” The problematic aspect of this “choraic possible” derives from the lack of determination and unity of Kristeva’s semiotic *chora*, as well as from its mobile and contradictory character. “The possible,” says Mikael Epstein, “is not the existing or its negation, it is not that which is or is not, it is a special mode of being that in general cannot be translated into the language of real or ideal existence” (Epstein, *The Philosophy of the Possible*, p. 9). Applying to Epstein’s definition of “the possible” to reflect upon Kristeva’s “choric possible,” the aporetic manifestations of the Kristevan’s subject are apparent. These manifestations are in line with the Platonic oxymoronic *chora*, the model used by Kristeva. *Chora* is, in its essence, always the space of aporia in which contradictions dwell. This conflictual space, “one of those violent, dark revolts of being,” generates abjection. Kristeva’s abjection is the response “directed against an exorbitant threat which seems to emanate from beyond the possible, the tolerable, the thinkable” (Kristeva 1982, *Power of Horror*, p. 1). Celebrating the writing of abjection (more exactly, that of Celine) – “possible at last” – Kristeva is responsible for a psychology of “the possible,” albeit a possible “beyond possible.” For Kristeva’s “possible” is “a sublimation of abjection,” a substitute for the role formerly played by the sacred,” and thus, a “sublimation without consecration” (Kristeva 1982, *Power of Horror*, p. 26). This oxymoronic possibility beyond all possibilities, beyond containment and assimilation, ultimately beyond the thinkable and the signifiable, turns its own subject vertiginously and inescapably against itself. Trapped in endless processual reinscriptions, the subject is constantly under trial, the trial “of that impossible [language] constituted either by a-subjectivity or by non-objectivity” (Kristeva 1982, *Power of Horror*, p. 26).

Possible at Last

Poetic Language and the Subject in Process Between Psychosis and Creativity

What makes the work significant, writes Kristeva, is the textual presence – poetic language, which

bears a more basis significance that has to do with our being-in-the-world (Kristeva 1974, RPL, p. 7).

“Poetry,” argues Kristeva, “more precisely, poetic language – reminds us of its eternal function; to introduce through the symbolic that which works on, moves through, and threatens it. The theory of the unconscious seeks the very thing that poetic language practices within and against the social order; the ultimate means of its transformation or subversion, the precondition for its survival and revolution” (Kristeva 1974, RPL, 81).

The idea that poetic language constitutes a “semiotic system” must be taken only within Kristeva’s polarity of the symbolic and semiotic dispositions in the signifying process (Kristeva 1974, RPL, pp. 2–3). The revolution of the poetic language is Kristeva’s original idea, which refers to the changes in the poetic language at the end of the nineteenth century that allowed the subject’s dialectical state in language. The link between poetic language and revolution is neither causal nor immediate (Kristeva 1974, RPL, p. 3). Pointing out to the manifestations of the semiotic dispositions, Kristeva demonstrates “how closely their [poets’ and novelists’] writing practice parallels the logic of the unconscious, drive-ridden and dark as it may be; such a practice thus assumes that privilege of communicating regression and jouissance.” (Kristeva 1974, RPL, p. 3). In her view, poetic language refers to “the infinite possibilities of language, and [that] all other language acts are merely partial realizations of the possibilities inherent in poetic language” (Kristeva 1974, RPL, p. 2). Normative language is just one of multiple possibilities of expression and “ways of articulating the signifying process that encompasses the body, the material referent, and language itself” (Kristeva, RPL, p. 15). The semiotic space as an imaginative space “reveals that linguistic change constitutes change in the status of the subject” in the writer’s relation to the body, the others, and to the physical world. Only through poetic language, and its poetic logic, “by adopting a dream logic, [self] transgresses rules of linguistic code and social morality as well” (Kristeva 1980b, “Word, Dialogue, and Novel,” p. 70). This makes possible to express the double or multiple aspect of human subjectivity. One could also identify new dispositions and new possibilities of developing other modes of

conceiving the self through the imaginative activities. For Kristeva, when the speaking subject becomes a subject in process/in trial (*sujet en procès*), “deep structures or at least transformational rules are disturbed, and with them, the possibility of semantic or grammatical reinterpretation or transformation appears” (Kristeva 1974, RPL, p. 37). In her view, the subject must be firmly posited so that drive attacks against the thetic will not give way to fantasy or to psychosis but will instead lead to, what she calls a “second-degree thetic,” i.e., a functioning characteristic of the semiotic *chora* within the signifying device of language (Kristeva 1974, RPL, p. 50). This new possibility – “the (creative) possible” of the subject in process – is illustrated by the artistic practices, especially, the poetic language. From this perspective, the semiotic *chora* does not appear as a “failure of the thetic,” but it is its very precondition (Kristeva, 1974 RPL, p. 50). In psychoanalysis, neurotics and psychotics, argues Kristeva, are assessed in rapport with their relation with the thetic, where semiotic motility is viewed as a disturbance of language. Resisting to psychoanalysis means to hypostasize semiotic motility, to make it autonomous from the thetic, turning psychosis into a poetic act. Overturning psychoanalysis is, or could be seen, as Kristeva’s instantiation of the possible. It is a practice in which what the semiotic motility “pulverizes,” it could be a new device to provide a new possibility. This completely new and unexpected possibility would be “as if a text, in order to hold together as a text, did not require a completion [*finition*], a structuration, a kind of totalization of semiotic motility” (Kristeva, 1974 RPL, p. 51). In the new disposition of the subject, we have a manifestation of “the possible,” but only of the subject for whom the thetic is not a repression of the semiotic *chora*, but “a position,” taken or undergone that calls into question the thetic so that a new disposition and a new possibility is opened for the subject (Kristeva, 1974 RPL, p. 51).

Kristeva discovers unexpected possibilities of poetic expression even in Saussure’s *Anagrammes*, the surprising research of the father of the linguistic structure. Drawing some theoretical implications from Saussure’s *anagrammatic*

project, Kristeva shapes her own *paragrammatic* conception of poetic language as a free play and as an open-ended web of relations (Kristeva, *Séméiotiké*, p. 114). The *paragrammatic* disposition of the poetic language allows the signifier an unbounded semiological play instead of a mere referential function. It is what she saw in the Saussure’s *Anagrammes*, in which the sign introduces “the heretofore unrecognized possibility of envisioning language as a free play, forever without closure” (Kristeva, *Desire in Language*, p. 128). Saussure himself was impressed by the phonic elements from the Saturnine Latin passage looking as a swarming of syllables or phonic group echoing one another (Stawarska 2017, p. 134). Kristeva’s idea of rhyme and rhythm as patterns that mimic bodily drives validates Saussure’s idea that poetic verse is equipped with structure that does not only operate at the level of the linguistic units (syllables, phonemes), but also at the vocalic level (rhyme, rhythmic repetition). In the rhythmic and repetitive beat of the poetic verse, the externalization of the inner flow of physiological drives is expressed, and a breaking through of the logical structures, subverting language, and making the recitation of the poem memorable. For the world of thoughts has a model in the world of sentences, expression, words, signs, argues Kristeva:

“To the structure of the thought there corresponds the compounding of words into a sentence; and here the order is in general not indifferent. To the dissolution or destruction of the thought there must accordingly correspond a tearing apart of the words, such as happens, e.g., if a sentence written on paper is cut up with scissors, so that each scrap of paper there stands the expression for part of a thought. These scraps can be shuffled at will or carried away by the wind: the connection is dissolved, the original order can no longer be recognized. (Kristeva 1974, RPL, p. 121).

Summary

A mode to address “the possible” in Julia Kristeva’s work is from the perspective of her concept *chora*, inspired by Plato’s similar term from his dialogue *Timaeus*. It is important to stress first the open character of Kristeva’s semiotic *chora*, and of the choral phenomena that take

place in the semiotic *chora* in the process of the definition of the subject. Kristeva's signifying subject is never fixed, but always in process, or in trial. Always in conflict with the symbolic function, and in revolt against prohibitions, the subject constantly searches for new possibilities of expression. The affective and conflictual phenomena, such as sensation, mood, and memory, situation and accident exceed the law of signification and determination of the subject in process. Kristeva's *chora* makes room for the undetermined and undeterminable possible, challenging determination, fixity or stasis, and giving an insight into the extralinguistic processes, into the origins. In the absence of the semiotic *chora*, the humanities would remain "archivistic, archaeological, and necrophiliac" (Kristeva 1974, RPL, p. 13). Kristeva's view of art as the only means by which *jouissance* (pleasure) can infiltrate the symbolic order opens up to unexpected possibilities for signifying (poetic) subject. This is Kristeva's *poetic revolution* and the ground of "the possible" as a passage from semiotic violence to symbolic order, the event of sacrifice. The genesis of the subject is similar to "a scene of sacrifice" (Keenan 2005, *The Question of Sacrifice*, p. 33), and the artist comparable to the "scapegoat." Creation emerges as a process of transformation of the semiotic into the symbolic, always a process of becoming and in which the possible manifests itself. "If creation is, like its human subject, on trial, basically consisting in constantly confronting the choraic motility of the semiotic *chora*, then creation is that flow of *jouissance*, which is therapeutic" (Isar 2005, p. 106).

The Possible in the Life and Work of Lev Vygotsky

Ian Thompson

Department of Education, University of Oxford,
Oxford, UK

Abstract

The possible, in educational terms, suggests the pedagogical potential of schooling to help children and young persons to change their perceptions about their imagined worlds of the future. It also highlights the possibilities for learning and development for all. Yet

international evidence suggests that the potentials of many young people from economically and socially disadvantaged backgrounds and/or with a special educational need or disability are not currently met by many school systems. In addressing these issues, there is a considerable body of educational research in the fields of inclusion, social justice, and child and adolescent development that draws on the theoretical body of work developed by the Soviet psychologist Lev Vygotsky. Most of these studies draw on either sociocultural or cultural historical activity theory, both of which can be traced back to Vygotsky's work on learning and development with a respective focus on semiotic mediation and speech as a cultural tool or human activity systems. Both theories attempt to provide a nondualist account of the social, cultural, and historical factors that influence human development. This has important pedagogic implications for considerations of the processes and possibilities of teaching and learning.

Introduction

The possible, in educational terms, suggests the pedagogical potential of schooling to help children and young persons to change their perceptions about their imagined worlds of the future. It also highlights the possibilities for learning and development for all. Yet international evidence suggests that the potentials of many young people from economically and socially disadvantaged backgrounds and/or with a special educational need or disability (SEND) are not currently met by many school systems. In addressing these issues, there is a considerable body of educational research in the fields of inclusion, social justice,

and child and adolescent development that draws on the theoretical body of work developed by the Soviet psychologist Lev Vygotsky. Most of these studies draw on either sociocultural or cultural-historical activity theory, both of which can be traced back to Vygotsky's work in trying to provide "an account of learning and development as mediated processes" (Daniels 2005, p. 6) with a respective focus on semiotic mediation and speech as a cultural tool or human activity systems. Both theories attempt to provide a nondualist account of the social, cultural, and historical factors that influence human development. As Daniels (2005) points out, this mediational account avoids "determinism in that they both acknowledges that in the course of their own development human beings also actively shape the very forces that are active in shaping them" (6). This has important pedagogic implications for considerations of the processes and possibilities of teaching and learning.

Vygotsky produced an extraordinary body of work for someone who was only active as a researcher and psychologist between 1924 and 1938. This chapter will briefly place Vygotsky's psychology in context and then address some of these key insights from Vygotsky's revolutionary psychology and the implications for the possible in education. In particular, attention is focused on: Vygotsky's educational psychology on the development of mind in society; the concepts of the zone of proximal development and the social situation of development; and the relationships between the affective, imagination, and cognition.

Vygotsky's Psychology in Context

Vygotsky sought in his research to understand the development of mind in society (Daniels 2017; Kozulin 1999; Van der Veer 2014). One of Vygotsky's (1987) theoretical insights is that the development of mind involves mediated activity through psychological tool usage and in particular the culturally acquired conceptual tool of language. For Vygotsky (1987), learning leads development. Both learning and development are

mediated through interactions with other people and through the social and cultural acquisition of sign systems. In Vygotsky's view, individuals are both active agents in their development and shaped by contexts and available tools. In order to understand the revolutionary implications of this nondualist position for educational psychology, it is useful to briefly place his work in its historical and cultural social context.

Vygotsky's development as a psychologist and researcher took place in the contexts of the turmoil facing postrevolutionary Russia with the pressures of civil war and his own struggle against the effects of tuberculosis that led to his death in 1934. Vygotsky began his systematic work in professional psychology in Russia in 1924 at the age of 28 having previously been a student of law, literature, philosophy, and clinical psychology and both a secondary school teacher and college lecturer (Holzman and Newman 1993). Vygotsky also became personally involved in trying to provide education for those displaced by the First World War and the civil war that followed the October Revolution. For example, Vygotsky taught evening classes to laborers and later helped to found the Institute of Defectology in Moscow. Vygotsky was appointed to work in the People's Commissariat for Public Education with the remit of developing a state system to educate children with special needs or who were homeless and who had been "pedagogically neglected" (Yaroshevsky 1989, p. 96). Vygotsky's response was to attempt to develop a Marxist theory of human development that had pedagogical implications for all learners.

However, Vygotsky's theoretical insistence on the potentially agentic role of individuals within society placed him at odds with the increasing dominance of Stalinist deterministic orthodoxy. It is no accident that Vygotsky's works were largely suppressed in Russia after his death and his writing did not become well-known in the West until the 1970s. Translations of Vygotsky's texts into English and other languages remain contested over questions of accuracy of both meaning and text composition. Yet Vygotsky's work continues to exert important influence

particularly in the fields of child development and education because of its focus on potential and possibilities.

Vygotsky's Educational Psychology

Vygotsky sought a unified approach to understanding the development and uses of higher psychological processes. Vygotsky (1987, 1993) explicitly argued against the notion that child development is the result of a gradual acquisition of unitary changes. Instead, development involves a complex dialectical process involving the interaction of internal and external factors as the child learns to overcome difficulties. Vygotsky argues that human consciousness is achieved by the internalization of shared social behavior. In educational terms, this suggests that the organization of learning in the classroom needs to take account of the cultural and social contexts that shape a child's development and the mediating role of teachers, peers, and cultural artifacts in that transformation. Wartofsky (1979) defines artifacts as things that humans create in three distinct areas: primary artifacts (words, writing instruments, etc.), secondary artifacts (beliefs, norms, etc.), and tertiary artifacts (imagined worlds, play, creative representations, etc.).

Vygotsky sought to establish a theoretical framework that viewed the mechanism of individual psychological development (behavior and consciousness) as being rooted in the society and culture that a person lives in and in terms applicable to natural sciences. Education is not simply a question of accumulating knowledge but of developing students' ability to think independently and through social interaction. The point to stress here is that cognitive development is neither simply determined by external forces nor limited by perceived fixed levels of cognitive ability. On the contrary, development is possible for all but only in the context of social environments that challenge and develop conceptual thought. Social context therefore is crucial to an understanding of human development as it is both through interaction with other people and our response to our material conditions that we learn to make sense of the world.

A major theme of Vygotsky's theoretical framework is that social interaction and cultural context play a fundamental role in the development of cognition. The development of higher order functions such as voluntary attention, memory, and concept formation is first culturally acquired through interaction with others and then internalized as thought. In addition, Vygotsky's theory attempts to explain consciousness as the end product of socialization. For example, in the learning of language, our first utterances with peers or adults are for the purpose of communication, but once mastered they become internalized and foster inner speech. Symbolic activity has a specific organizing function that is linked to the process of tool use in a child and produces fundamentally new forms of behavior. For instance, small children solve practical problems with the help of their speech, as well as their eyes and hands. The relative amount of egocentric speech, the transitional form between external and internal speech, increases in relation to the difficulty of the child's task. A significant moment in the course of intellectual development of the human occurs when speech and practical activity converge. This gives birth to the specifically human forms of practical and abstract intelligence of the ability to use and manipulate both tools and speech.

Vygotsky (1987) points out that sign using activity in children is neither simply invented by the child nor passed down by adults but involves the child going through a complex set of mediated activities that help to develop higher psychological processes. The history of the sign in humans (e.g., use of tools and human speech) is that they are transitional systems that lie between the biologically given and the culturally acquired. This is why Vygotsky places childhood and adolescence at the center of the history of cultural development. As children develop physically, they acquire through social interaction the intellectual ability to use the fundamentally human sign system of language which in turn enables them to transform their surroundings. While these two forms of tool usage are qualitatively different, they nevertheless overlap and together produce new forms of human behavior. Vygotsky (1987)

argues that signs have both communicative and intellectual functions. As signs become speech, they become the psychological tools of higher mental processes such as abstract thought. Here, Vygotsky does not crudely equate language with thought but explains the complex process by which the two intertwine during a child's development when thought is verbalized and speech becomes intellectual. He distinguishes four phases in this development.

1. Where speech and intellect develop separately and on a primitive level
2. When the child begins to master basic problem-solving and speech develops syntactically but may not be used accurately
3. When problem-solving is aided by the control of egocentric speech and symbolic representation
4. When the child then internalizes thought both intellectually and verbally through inner speech

Egocentric speech and symbolic representation imply an audience, or other, and it is through the mediated negotiation of meaning with this other that the child develops thought processes. The use of word images or symbols requires a degree of analytical control as the child must organize sounds into words and words into sentences to create meaning as opposed to the spontaneity of oral speech. Vygotsky in this theory broke from the existing view that saw cognition and language as readily formed in the structure of the brain. As language and thought have developmental functions, context has a formative role. It matters where and how we learn as well as who we learn from.

Although many cognitive developments take place in early childhood, Vygotsky argued that other higher-order psychological processes, such as concept formation, only emerge at secondary school age. This provides the theoretical basis for learning in the secondary school. If for the adolescent the process of recall means to think or conceptualize, then curriculum design needs to provide opportunities for this process to occur through a process of dialogue between teacher

and pupil or between the student and peers that builds on the previous experience of the pupil. The development of thought, rather than the handing over of specific knowledge, is where real educational learning takes place. Vygotsky argued that school learning introduces something fundamentally new into students' development. Vygotsky saw the importance of children's learning of scientific concepts not as ends in themselves or the highest forms of knowledge but as the acquisition of tools for argumentation and understanding of the world around them. By giving students specific tasks of understanding scientific concepts within a designed environment, school learning introduces new concepts that can, in turn, stimulate psychological development. It is within the dialectical interplay between the students' grasp of everyday or spontaneous concepts and the development of their scientific conceptual understanding that learning leads development. However, simply giving students tasks or allowing them to communicate does not guarantee learning, particularly for those students who are most resistant because of previously negative experiences. While learners' needs must determine classroom activity, it is through appropriately structured activity that students learn. As Derry (2008) points out, the learning environment has to be designed according to a clearly-designed conceptual framework of learning if the possible is to be realized.

The Zone of Proximal Development

The Zone of Proximal Development (ZPD) is perhaps both the best known and perhaps least understood concept in Vygotsky's thought. Unlike the predominant model of children's learning that sees the function of learning as acquisition of knowledge, Vygotsky's theory of the ZPD stresses the importance of the educative process in the psychological development of higher-order thinking. For Vygotsky, the ZPD is the difference between existing and potential levels of development revealed through an analysis of how far a student is able to master a task by themselves or with mediational help from another such as a

teacher or peer. This is a radically different position from theories that claim that intellect results from maturity alone. It also challenges the very notion of what constitutes intelligence from accepted views of levels of acquired knowledge as indicators of potential toward an understanding of the importance of the processes and development of cognitive thought.

In his writings, Vygotsky variously viewed the ZPD as a tool for both academic and psychological assessment that could lead to the development of mental processes through mediated activity (Wertsch 1985). As Chaiklin (2003) has argued, Vygotsky's concept of the ZPD defines the potential *development* of a child rather than an abstract metaphor for learning. For Vygotsky, real learning is that which is in advance of development and is mediated through interactions with other people and through the social and cultural acquisition of sign systems. The ZPD indicates both the presence of maturing psychological functions and the possibility of meaningful interventions that can stimulate conceptual development. This process of conceptual development involves cooperation and collaboration between the teacher and the learner, or between learners at different levels of development. For Vygotsky, collaboration and cooperation are crucial features of effective teaching. Vygotsky (1987) argued that learning can take place when the learning task is set at a level in advance of the student's current mental level of development.

Unlike the predominant model of children's learning that sees the function of learning as acquisition of knowledge, Vygotsky's theory of the ZPD stresses the importance of the educative process rather than the final outcome. This has implications for the design of classroom activity concerning the relationship between instruction, students' development, and the classroom environment. In an educational context, cultural-historical activity theorists argue that while learners' needs must determine classroom activity it is through appropriately structured activity that pupils learn.

The ZPD indicates both the presence of maturing psychological functions and the possibilities of meaningful interventions that can stimulate

conceptual development. This process of conceptual development involves cooperation and collaboration between the teacher and the learner, or between learners at different levels of development. However, Vygotsky's emphasis in the concept of the ZPD was on individual children within social situations of development.

The Social Situation of Development

Vygotsky's (1998) concept of the social situation of development is characterized by changes in personality and consciousness of the social world at critical periods in child and adolescent development such as "when they begin to walk and talk, when they start to use conceptual thinking, and when they gain self-awareness during adolescence" (Mahn 2003, p. 120). Vygotsky (1993) argued that this development involves a series of crises as the learner encounters contradictions between their own psychological development and the demands of the learning situation. When there is a clash between the personal and social, there are possibilities for the young person, through interaction with others, to begin to envisage things in a new way. However, these social situations of development can lead to considerable frustration for the young person as well as a "drop in the rate of success, a slacking of interest in school work, and a general decline in capacity for work" (Vygotsky 1993, p. 191). At adolescence, this frustration can also lead to clashes with authority, or the perceptions of parents or schools, as the young person develops a more critical understanding of previously-accepted cultural and social norms.

Vygotsky (1993) argued that in moments of crisis within a particular social situation of development "the child can become relatively difficult due to the fact that... the pedagogical system applied to the child does not keep up with the rapid changes in their personality (193–194)." These moments of crisis are both personal to the particular need and history of each young person but also socially experienced and mediated by interaction with others. Moreover, the key to development lies in the ability of an individual

to perceive the limitations of the situation they are in and to reimagine a different identity that allows them to function and thrive in social situations (Holland et al. 1998).

Imagination, Cognition, and Emotion

Vygotsky (1993) identified children and young people's emotional experiences, or their affective relationship to their environment, as a key unit of analysis for an understanding of their development. This has particular resonance for the possible in education for all children and young people but particularly for those from disadvantaged traumatic backgrounds or with SEBD. There is increasing awareness of mental health issues for many adolescents, particularly anxiety and depression that increase the risk of social isolation and difficulties in schooling. These fears are heightened by the social and emotional effects of school closures during the Covid-19 pandemic. At schools, teachers and parents debate the future of schooling post-Covid-19, issues of well-being become as important as academic attainment. Vygotsky's argument, in terms of future possibilities, is that these are not separate issues.

Yaroshevsky (1989) points out that Vygotsky perceived imagination, cognition, and emotion as being closely interrelated. He argued that imagination in adolescence is the successor of children's play and plays a key role in development. Imagination, invoked through the social situation of play and mediated through interaction with others, can help a young person to change their perceptions about the imagined worlds of the future. Engeström (2009), from the perspective of cultural historical activity theory, argues that analyzing emotional experiences can be a means of understanding "object-related motives that are difficult to access and explicate consciously" (308). This points to the importance of Vygotsky's theoretical framework for understanding the possible. Bozhovich (2009) explains that what "underlies complex and diverse emotional experiences—internally conflicting or ambivalent emotions—is a complex structure of diverse needs and impulses, diverse motivational

tendencies” (71). This is particularly true of young people with SEBD. Vygotsky (1991) explains that “imagination in adolescence is, from the developmental point of view, the successor of children’s play” (77). Imagination, invoked through the social situation of play and mediated through interaction with others, can help a young person to change their perceptions about the imagined worlds of the future. As Smagorinsky (2011) argues, Vygotsky’s “relation of imagination, emotion, and cognition suggests that people’s capacity to project a trajectory for themselves is culturally mediated. It is important to understand, then, the kinds of mediation that provide both the emotional foundation and cultural sense of propriety for their trajectories, and the sorts of mediation that potentially limit conceptions of trajectory” (339).

Within schools, the remedy offered to those who struggle to engage with an academic curriculum has traditionally been to offer more of what has failed in the first place, particularly in the areas of literacy and mathematics. However, there is a growing recognition that emotion and imagination are central aspects in the development both in very young children and in adolescence. Research has shown that arts-based interventions can be effective for some young people in certain circumstances (e.g., Thompson, 2015; Thompson and Tawell 2017) and that arts participation and creativity are potentially important foundations for well-rounded child and adolescent development.

Evoking play through storytelling, drama, music, or a range of other artistic activities can help young people’s ability to self-regulate, empathize with others, and work collaboratively. Arguably, developing these attributes is key to young people’s self-esteem and their ability, in turn, to tackle curriculum areas that they have found problematic.

Vygotsky’s theoretical conclusions on the links between effect and cognition have direct implications for pupils who struggle. Vygotsky (1993) and Luria (1981) specifically criticized schemes that isolate slow learners and teach mechanized learning programs because they fail to expose the child to abstract thought and focus exclusively on concrete thinking. Vygotsky emphasizes that

education for all children is a social process where dialogue and the language of instruction should be designed to stimulate internal developmental processes needed for future learning. The assimilation of a word or the mastery of arithmetic operations is not the end of the developmental process but the basis for development of complex thought processes.

Vygotsky’s insistence on the importance of play in mental development suggests that the classroom environment itself needs to be addressed. However, there is a marked difference between the play of a preschool child and that of the adolescent in school where play is mediated through systems of school instruction and rules. The important point for Vygotsky is that play does not disappear in adolescence, but rather that imagination influences attitudes toward reality. The role of play, or of the process of a child engaging with a concept through apparently abstract activity, remains of paramount importance. Imagination (play) arises from action. Vygotsky argues that while there is no such thing as play without socially constructed rules the central attribute of play is a rule that has become a desire. Play gives a child new forms of desires and motives so creating possibilities for both emotional and cognitive development. School instruction can mediate this process by introducing new methodologies to the child that stimulate abstract thought through the social context of playing with and manipulating the stimulus provided.

Summary

Vygotsky’s educational psychology hints at the developmental possibilities of education. Vygotsky conceived learning as both a social and situated cultural activity. For Vygotsky, real learning is that which is in advance of development and is mediated through interactions with other people and through the social and cultural acquisition of sign systems. This theoretical framework views individual psychological development as being rooted in culture and society (the social situation of development). It is both through interaction with others and our response to the contexts within which we develop that we

attempt to make sense of the world around us. Learning involves mediated activity through psychological tool usage and in particular the culturally acquired conceptual tool of language.

The ZPD indicates both the presence of maturing psychological functions and the possibility of meaningful interventions that can stimulate conceptual development. This process of conceptual development involves cooperation and collaboration between the teacher and the learner, or between learners at different levels of development. Vygotsky argued that school learning introduces scientific concepts within a designed environment can help to stimulate psychological development. It is within the dialectical interplay between the students' grasp of everyday spontaneous concepts and the development of their scientific conceptual understanding that learning leads development. Vygotsky identified emotional experience, or the young person's affective relationship to their environment, as the key unit of analysis for an understanding of this development. It matters both who we learn from and with as well as how and where we learn and in what social, cultural, and historical context. For Vygotsky, imagination, cognition, and emotion are closely interrelated. This has implications concerning the relationship between instruction, students' development, and the classroom environment. Learning must also involve risk and uncertainty if young people are to learn through their engagement with social situations of development. In this sense, the cultures of institutions that resist pressures of performativity are key to potential development of marginalized learners. The challenge for educators is to find ways to reinvigorate the imaginations of young people that are essential for their social, emotional, and cognitive development.

The Possible in the Life and Work of Ludwig Wittgenstein

Abstract

Wittgenstein's philosophy is developed in two different stages. However, his conception of the nature and goals of philosophy reflects no change in essence: he denies there are genuine philosophical problems, and hence, philosophical knowledge. When a certain philosophy is presented as a body of knowledge or questions, as happens in traditional philosophy, Wittgensteinian philosophy shows there is a confusion at the ground. Traditional assertive philosophy can be seen as an "illness" or "disease" and Wittgensteinian philosophy as a peculiar activity, as a "therapy." Therapeutic philosophy relies on a diagnosis of the source of philosophical problems, which arise because the logic of language is not clearly understood. Changes in Wittgenstein's philosophy depend on developments in Wittgenstein's own understanding of the logic of language. In *Tractatus Logico-Philosophicus* (1921), elucidation of meaningful language has its core in the bipolarity of propositions (its necessarily true or false character). This starting point leads to the notion of a "logical space" (all possible "states of affairs") and to the crucial notion of a "logical form" shared by all meaningful language. *Philosophical Investigations* (1953), on the contrary, starts from the many different actual uses of language and offers a much broader conception of meaning. Wittgenstein's main concept in this work is "language game." As he has previously shown for games, neither do language games rest on an underlying essence below the multiplicity of particular linguistic activities. Languages games relate to each

other by way of a complicated network of similarities and differences, among which are "family resemblances." Wittgenstein develops this entirely new conception on the basis of a critique of his previous view, also implying a new understanding on logic and possibilities.

Introduction

Ludwig Wittgenstein was born in Vienna in 1889, the last child of a wealthy and cultured family. The house of the Wittgensteins was a center for artistic life, which strongly influenced the young Ludwig with the cultural atmosphere of "*fin de siècle*" Vienna. Wittgenstein started to study Engineering in Berlin in 1906, moving to Manchester in 1908. He soon became captivated by the problem of the foundations of mathematics as presented in the work of Frege and Russell. In 1912, following Frege's advice, Wittgenstein went to Cambridge to study with Russell. In 1913, he went to Norway to develop his ideas in solitude. With the outbreak of World War I, he returned to Vienna and joined the Austrian Army. As a soldier, Wittgenstein managed to continue working on what was to become his *Tractatus Logico-Philosophicus*. In 1918, while being held prisoner, he was able to send Russell his manuscript, which was eventually published in 1921 in German, and translated into English in 1922.

The book was very influential, both because of its acute criticisms of Frege and Russell and its reception in the "Vienna Circle," although Wittgenstein's inspiration and goals differed widely from those of logical positivists' (see Lecourt 1981, pp. 141 ff.). Convinced that his *Tractatus* had solved the basic problems of philosophy, he abandoned philosophy and devoted himself to several different jobs (rural elementary teaching, gardening at a monastery, architecture). By the end of the 1920s, and because of his discussions with young English mathematician

Frank Ramsey and some members of the Vienna Circle, he became unsure of some aspects of the solution proposed in the *Tractatus*. He therefore returned to Cambridge in 1929, where was also influenced by Marxist economist Piero Sraffa, and thus, what was originally intended to be a modification of some aspects of the *Tractatus* became a radical rethinking and strong criticism of his former views. As a result, he produced a fundamentally different outlook, the major expression of which is found in his *Philosophical Investigations*, published posthumously in 1953.

Tractatus Logico-Philosophicus

The Preface to *Tractatus* opens with a consideration concerning the possible, which concerns the limit of thought. Can we separate what is thinkable from what cannot be thought? If that were to be done directly, trying to think the unthinkable or the impossible, the result would be an obvious contradiction. Wittgenstein then traces the limit indirectly, exploring the limit to the expression of thoughts, in other words, of language. In this way, “what lies on the other side of the limit will simply be nonsense.” (Wittgenstein 2001, p. 4).

Drawing the limit indirectly differs from doing so directly because what is involved when a sentence is called nonsense is not like the paradoxical discovery of a sense that has the property of being senseless. That would replicate the difficulty at semantic level. When a sentence is referred to as nonsense, the sentence is still an ordinary fact in the world (a chain of words) that does not have a sense attached to it because it violates the immanent legality of language. For instance, the sentence “The pencil is friendly” is not a proposition, it is simply nonsense.

Now, in order to recognize that a chain of words is nonsense, it is necessary to be acquainted with language. Based on this acquaintance, given a proposition, it cannot be known in advance whether it is true or false, but there is no doubt as to what is required for the proposition to be true. Given the proposition “The pencil is blue,” it is not possible to know *a priori* whether this is true or false, but in contrast, there are no doubts as to

the fact that would make the proposition true. The proposition is a picture (*Bild*) of a fact, and while, by looking at the picture (proposition), we cannot tell whether the pictured fact actually happens, we immediately understand what should happen for the picture to be true. Since this is clear, the proposition is bipolar: either this fact actually happens, and the proposition is true, or this fact does not happen, in which case the proposition is false.

All this means that the indirect drawing of the limit depends on a presupposition. The absence of doubts concerning the sense of a proposition, its bipolarity, allows us to draw the limit immanently, from inside the language, distinguishing propositions from senseless sentences. This presupposition can be clarified.

Wittgenstein starts the *Tractatus* with the proposition “The world is all that is the case.” (2001, prop. 1¹). He immediately commentates it: “The world is the totality of facts, not of things.” (2001, prop. 1.2). This commentary goes against intuition, but Wittgenstein states it to show that the bipolarity of propositions implies that every fact is contingent, that there are no necessary facts. But he believes also that the difference between sense and nonsense shows that every contingency is located within the framework of a fully determined set of possibilities.

This depends on the distinction between objects (things) and facts. Objects play a crucial role in the constitution of facts, but they are not facts. If objects were “the case,” if they were effectives, then their possibilities for combinations would be contingent. However, the difference between sense and nonsense shows that not all combinations of objects are possible. Our certainty concerning whether a sentence is nonsensical or a proposition shows that the possibilities as a whole are not contingent.

¹The *Tractatus* is organized into propositions where the decimal numbers indicate their importance. As Wittgenstein explains in a footnote: “The propositions *n.1*, *n.2*, *n.3*, etc. are comments on proposition no. *n*; the propositions *n.m1*, *n.m2*, etc. are comments on proposition no. *n.m*; and so on.” (2001, p. 5).

Wittgenstein explains that the world is divided into facts (2001, prop.1.2), each one mutually independent of the other (2001, prop. 1.21), and that a fact is the existence of “states of affairs” or “atomic facts” which are not composed of other states of affairs, but of a combination of objects. Objects do not exist by themselves, but only in combination with other objects, i.e., in states of affairs. It is possible to imagine an object in itself, for instance, a rod or a ball, as if it had an inner essence. But indeed, a thing or object cannot be imagined without thinking of its possibilities (and impossibilities) of combining with other objects. The rod can be leaning against the wall, but not the ball (Wittgenstein 1998a, p. 70). These possibilities and impossibilities are constituents of an object’s nature. An object’s nature is exhausted by its possibilities for connections to other objects to form states of affairs. Wittgenstein can thus metaphorically say: “Logic deals with every possibility and all possibilities are its facts” (2001, prop. 2.0121) (see entry “► Possible in Logic”).

The actual combination between objects, the existence of states of affairs, is contingent, but the possibility of combination, the state of affairs in itself, is not. Therefore, Wittgenstein thinks that given all the objects, the entirety of possibilities of states of affairs is also given. The totality of objects is the “substance” of all possible worlds (what remains unchanged below the changes) (see entry “► Possible Worlds”). Wittgenstein calls this “logical space.” Logical space “contains” all possible states of affairs. Indeed, logical space is not a container in which objects are located, because the relationship between objects and logical space is not external, as is that between the container and its content, but internal. The very structure of logical space depends on the objects that compound it.

This leads Wittgenstein to state that logical objects are not what would ordinarily be called objects (like a clock, a pencil, or a table) which are complex, because logical objects are simple. If they were not simple, then the bipolarity of a proposition would collapse and it would be impossible to make a picture of the world. What is involved here is the logical role of names. Names do not describe, and they only refer to

objects. But if a name could refer to a complex, then the sense of the proposition would be uncertain, because it would depend on the connection of the constituent parts of the complex referred to by the name, and this connection would be a contingent fact. Thus, the sense of a proposition would depend on whether another proposition was true. In order to sketch a picture of the world, it would be necessary to know what world is being referred to. For instance, if the expression “King of France” were the name of an object, the proposition “The King of France is bald” would have different senses in different possible worlds. It would have one sense in a world where there is a King of France, and it would be senseless in a world where there is not. Logical analysis shows that, in cases like this, superficial grammar does not correspond with the deep logical structure of the proposition, something that Russell pointed out before Wittgenstein. The analyzed structure of the above example would be roughly: “There is one and only one individual who is at the same time King and French, and he is bald.” where it is clear what the case should be, and which is false in the actual circumstances. To summarize, if objects were not simple, the world would not have the permanent form which makes it possible to describe it.

The conclusion that the actual combination between objects is contingent, but that the possibility of their combination is not, is the cornerstone of the *Tractatus*. It supports the pictorial theory of the proposition and its crucial concept of “logical form.” A picture is a fact which models another fact. A picture has two dimensions: (1) the “pictorial relationship,” which correlates elements of the picture with objects in the world (see 2001, props. 2.1513 and 2.1514) and (2) the “structure” of the picture, i.e., the connections among its elements, which depicts the way in which the elements in the depicted fact are displayed.

The pictorial relationship equates to the correlation between names and objects. But a picture must have something in common with the depicted fact, a structural similarity, and this is clarified by way of the concept of a “pictorial” or “representational” form. As Wittgenstein says: “A picture can depict any reality whose form it has. A

spatial picture can depict anything spatial, a colored one anything colored, etc.” (2001, prop. 2.171). For instance, a spatial picture (like a map) can depict the spatial relationship among the elements of the depicted fact (a territory).

In order to be able to represent something, a picture has to be a fact. Propositions, like any other picture, are facts. They are pictures because they establish a figurative relationship with the world, the names of propositions refer to simple objects, have them as their meaning (*Bedeutung*), and combine these names in a particular form that exhibits the putative relations of the objects in the fact depicted. But if a spatial picture shares a “pictorial form” with the special fact it depicts, it is clear that propositions do not share any concrete form of reality with their depicted facts. Nevertheless, because both proposition and depicted fact are facts in the logical space, they have in common at least the logical form of reality.

Just as a spatial picture uses the spatial relationship between its elements to show what the depicted fact is like, but cannot depict this spatial relationship, propositions show in their logical form what depicted facts are like, but cannot say anything about the logical form, other than simply showing it.

Elementary propositions that depict states of affairs combine to form molecular propositions. Molecular propositions are truth-functions of elementary propositions, that is to say, the truth of a molecular proposition depends exclusively on the value of the elementary propositions integrating it. This theory allows Wittgenstein to show that logical constants (quantifiers and connectives) are not the names of logical objects but truth-functional operations of elementary propositions.

Although elementary propositions are always contingent, there are some special cases of truth-functional molecular results which are not contingent. This is the case of propositions in logic. Propositions like “It is raining or not raining” are necessarily true because of their structure, they are tautologies. Tautologies such as this example that say nothing about the weather say nothing in general about the world. Nevertheless, they show something about it, its logical form: a proposition that excludes nothing is senseless.

Contradictions which exclude all possibilities are also senseless.

The general form of the proposition is things are thus-and-so (see Wittgenstein 2001, prop. 4.5, and 2009, § 134; all references preceded by “§” are taken from Part I of *Philosophical Investigations*). Tautologies and contradictions show the limits of the logical form of the proposition. Tautologies and contradictions respectively expand and restrict the “thus-and-so” of a proposition excessively, and consequently cancel out the essential bipolarity on which logical form depends. However, they are not nonsense, because they do not violate any of the rules of language. In contrast, metaphysical propositions are, in effect, nonsensical; they try to state what necessarily has to be (for instance, that a semiquaver is a sound and cannot have weight). They try to describe the relationship between language and world as if it were a fact, thus contravening logical form and producing nonsense. What metaphysical propositions try to say cannot be said, it can only be *shown* by genuine propositions (that exhibit that the name “semiquaver” can combine with some names and not with others).

Although it has some similarities with it, Wittgenstein’s *Tractatus* philosophy is not a transcendental philosophy. At best, it can be seen, following an idea by Habermas, as non-affirmative transcendental philosophy (see Habermas 1982, p. 246). Transcendental philosophy consists of two movements. On the one hand, starting with something given as certain, it performs a regressive movement to its conditions of possibility. On the other hand, it tries to show how these conditions can be rationally justified. In Kant’s philosophy, we are told that we should not only think in terms of causality, as a question of fact, as if it were a sort of psychological compulsion, but that we are entitled to do so, because objects of knowledge actually have causes (see Stroud 1968). In other words, transcendental philosophy offers a legitimating condition of possibility. “Non-affirmative transcendental philosophy,” in contrast, does something like the first movement, elucidating what is entailed in the bipolarity of proposition, but avoids the second, legitimating movement. Indeed, it does not

“refuse” the second movement, but shows that it is impossible, that it is not a real option, that it only appears to be necessary because of confusion. In the *Tractatus*, the distinction between saying and showing renders the metalanguage in which the legitimating conclusion should be formulated impossible. In the penultimate remark of the book Wittgenstein reflects on this point using a simile: “My propositions serve as elucidations in the following way: anyone who understands me eventually recognizes them as nonsensical, when he has used them—as steps—to climb up beyond them. (He must, so to speak, throw away the ladder after he has climbed up it.) He must transcend these propositions, and then he will see the world aright.” (2001, prop. 6.54).

Philosophical Investigations

In *Philosophical Investigations*, Wittgenstein again does not conceive philosophy as a piece of doctrine but as a form of therapy. The best way of introducing later Wittgenstein ideas is to consider the particular illness *Philosophical Investigations* has to deal with, which is what remains of traditional philosophy in his previous views.

Philosophical Investigations does not take philosophical confusion as relating to one or another individual philosopher. Instead, Wittgenstein focuses on what he calls “pictures” (*Bilden*). Pictures condense orientations to raise questions and the kind of answers accepted as satisfactory. As rough conceptual devices, pictures can be refined in different ways. Hence, Frege’s semantic theory and the logical atomism of Russell and Wittgenstein can be seen as sophisticated developments of the Augustinian picture (see Glock 1996, pp. 41–45). However, when the inadequacy of a picture is perceived, we cease to be dominated by the temptation of refining it. Put differently, a picture establishes the way in which things “must or have to be” (see Wittgenstein 2009, § 66) in such a way that while we are captivated under their spell, the picture’s difficulties and flaws seem simply to be minor puzzles to be resolved in ways predetermined by the very same picture.

Philosophical Investigations opens with a fragment of the Augustinian *Confessions*, which presents one of these pictures. There, Augustine remembers his own acquisition of language. Augustine’s recollections summon a picture of how language works and what it is for words to have meaning. Wittgenstein sums this picture up in this way: “These words, it seems to me, give us a particular picture of the essence of human language. It is this: the individual words in language name objects – sentences are combinations of such names. In this picture of language, we find the roots of the following idea: Every word has a meaning. This meaning is correlated with the word. It is the object for which the word stands.” (2009, § 1).

According to Augustine, semantic understanding would consist of grasping the right connection between things and words, in such a way that, once the understanding is achieved (the grasping of the connection) the learning difficulty would be merely practical, external to understanding: getting accustomed to adequately pronouncing the sounds required for social interaction. Then, understanding and action are thought of as being conceptually detachable or externally related, bearing a contingent relationship to one another.

The Wittgensteinian analysis combines two movements. On the one hand, a movement of interrelated *diagnosis* and *criticism*, where Wittgenstein tries to find the source from which the picture emerges and becomes plausible (diagnosis) and to undermine the picture’s plausibility by pointing at its ensuing absurd consequences (criticism). On the other hand, there is a moment of *reconstruction* or *grammatical elucidation*, in which Wittgenstein tries to help whoever is captivated by a picture to become aware of what of what they already know, pointing out that when they try to represent this “already possessed knowledge,” they reveal they are unaware of it in a certain sense (see 2009, § 89).

The Augustinian picture tries to cope with a peculiar feature of our linguistic behavior already recognized in the *Tractatus*: *we usually have no doubts concerning the meaning of our expressions*. In traditional philosophical terms, what we are dealing with here is the classical distinction

between the *a priori* character of semantic questions and the *a posteriori* character of factual questions. Consequently, a number of philosophers have assumed that their central tenet was to provide an account of the *a priori* character of meaning and understanding. The ordinary philosophical way of accounting for this difference was by providing a justificatory ontology. This should provide a domain of meaning (ideas, concepts, mental images, objects, etc.) to guide and justify the speaker's actions. This would endow speakers with a certain knowledge, the nature of which is expressed in the *a priori* character of the understanding or "knowledge of meaning."

Later Wittgenstein realizes that in the *Tractatus*, this strategy could not be entirely avoided. The paradoxically rhetorical structure of the book, with its concluding metaphor of the ladder, prevented it being taken as a philosophical justification of language understanding. But it still remained too concerned with philosophical strategy, attempting to develop an ontology emerging from a feature of our ordinary practice. When later Wittgenstein says "don't think, but look!" (2009 § 66), he is no doubt thinking of the *Tractatus* strategy.

Wittgenstein then attacks the core of the Augustinian picture: the strong inclination to consider that understanding of language happens apart from actions. The application – the material actions performed by individuals in language games – would derive from something like ideas and mental states. On the one hand, Wittgenstein shows that these "ontologies of understanding," *are not sufficient conditions of understanding*. That is to say, the putative "ontology of understanding X" (e.g., mental states) can occur in any particular situation without this being a case of understanding X. On the other hand, Wittgenstein shows that the putative states (or acts) of understanding *are not necessary conditions either*, i.e., the underlying ontology can be absent and the case can nevertheless be a genuine case of understanding (see 2009 §§ 33–34, 73–74, 139–140).

What makes the Augustinian picture untenable is that it necessarily generates a duplicity of criteria for understating (mental states and applications) in potential contradiction with each other.

If the state identified at the beginning as the understanding of, for instance, "cube," (e.g., the "coming of the picture of a cube before our minds" see 2009 § 139) gives way to an application that contradicts the identification we have made (e.g., its application to a triangular prism), shall we continue to say that this is the state of understanding such and such? Wittgenstein's answer is clear: application is the basic criterion of understanding: "What is essential is to see that the same thing can come before our minds when we hear the word and the application still be different. Has it the same meaning both times? I think we shall say not" (2009, § 140).

Moreover, Wittgenstein's insistence on application as the main criterion of understanding implies a further consequence: we attribute understanding through agreement in judgments. The Wittgensteinian approach opens up some questions. On the one hand, insistence on the need for agreement on judgments seems to abolish the internal relationships of the link between the rule (the meaning) and its cases (its applications). For instance, when developing the series of even numbers, the correlation between 1002 as following on from 1001 is not a contingent relationship; it is not a question of observing the behavior of some others in the community to see whether they agree or not that 1002 follows on from 1001. Nevertheless, this seems to be a consequence of Wittgenstein's approach, as he himself recognizes in 2009, § 242: "If language is to be a means of communication there must be agreement not only in definitions but also (queer as this may sound) in judgments. This seems to abolish logic, but does not do so."

To clarify this point, we need to pay attention to an apparently paradoxical feature of Wittgenstein's way of exposition: the fact that his arguments collide with incredulity every time the text speaks in the first person. Because of this, the same arguments have to be presented over and over again (namely ostensive explanations, mathematical series, the relationship between will and actions, seeing aspects of a thing, etc.). It is worth mentioning here that the rhetorical articulation of *Philosophical Investigations* has been compared by K. T. Fann to a "confession." This means that

the entire work is dominated by a dialogue between the voices of “temptation,” which appears characteristically in the first person, and the voice of “correction” addressing it (see Fann 1969, pp. 106–107; Cavell 2002, pp. 70–71).

The “voice of temptation” characteristically points out that s/he understands merely by herself, without appealing to reminders of actual applications and independently of applications by others of the algebraic formula. The “voice of correction” shows that nothing can justify this certainty. The dialogue develops in this essential tension. There is a reason for this: the voice of temptation, besides its lack of justification as a theoretical vision, positively exhibits one of the constitutive requirements that makes someone a speaker of a language, without which what we know as language would cease to exist. The “voice of temptation,” though unjustified from a theoretical point of view, is not wrong from a practical standpoint (“To use a word without a justification (*Rechtfertigung*) does not mean to use it without right (*Unrecht*)” 2009, § 289).

Wittgenstein further developed this aspect by asking himself whether the persistent need for advancing the same kind of arguments due to the untiring capacity of the Augustinian view being reformulated, is not, in some way, part of the solution of the puzzle. According to Rush Rhees, in the “Preface” of *Brown and Blue Books*, this was what caused the development of *Philosophical Investigations*. Wittgenstein had already put forward the conception of thinking as “operating with signs” (Wittgenstein 1998b, p. 6, 15) in the *Blue Book* (1933–1934). But Wittgenstein’s uneasiness with this conception was growing and led him to consider issues such as “aspect-seeing,” “meaning and color blindness,” and “tone-deafness.” The point involved is: “does the perception of meaning fall outside the use of language?” (Wittgenstein 1998b, p. xiv). To assign a grammatical place to the perception of meaning is crucial because: “So long as there are such difficulties, people will still think that there must be something like an interpretation. They will still think that if it is language then it must mean something to me” (Wittgenstein 1998b, p. xiv).

The “voice of correction” shows that the “absence of doubts” concerning meaning cannot be justified. Consequently, first person findings of unity and necessity, which seems to warrant the performance of the speaker, are only of an imaginary character. But it does not mean that they could be abandoned as a mere illusion. Quite the contrary, the subjective certainty expressed by the “voice of temptation” is a primitive and necessary datum of Wittgenstein’s grammatical elucidation. This imaginary relationship between speakers and their conditions of existence as such (i.e., with the whole practice of the language games) is basically constitutive of their condition as “speakers.”

In a pedagogical relationship, for instance, understanding is attributed on the basis of the agreement between the pupil’s answers with those the teacher is inclined to give. The attribution of a statement like “S/he understands X” functions as a “rite of passage” (similar to the rite of passage from puberty to adulthood), by way of which the pupil receives a new social status. Now, one of the conditions the teacher will pay attention to when making a statement such as “The pupil understands X” is the student’s practical certainty in solving the tests s/he is submitted to. In other words, the absence of doubts and hesitations works as a criterion for the teacher when attributing understanding to her pupil.

Once the status of a particular understanding is granted, as in the case of the teacher, or of the pupil once s/he passes the tests s/he is submitted to, the individual is allowed to take as correct the answers s/he feels secure in giving without any further justification other than this confidence. Despite this authorization, s/he can still be corrected by others.

Conceived in this way, communitarian agreement differs from its usual understanding in American pragmatism (see entry “► [American Pragmatism](#)”). Agreement in judgments does not abolish logic because it offers no communitarian guarantee for a given practice or language game. Social agreement only implies that in practice the occasion for attributing disagreement is not actually activated. Social agreement, so understood, is tantamount to stressing that criteria are immanent

to different practices or language-games, logic included.

Deed · Responsibility · Given · Tasked

Russian philosopher of dialogism, responsible deed (postupok), and carnival, Mikhail M. Bakhtin

(November 4 (16), 1895, Oryol, The Russian Empire – March 7, 1975, Moscow, the USSR) worked with the literary material of masterpieces by Dostoevsky, Rabelais, Goethe, Gogol, and so on. Bakhtin did not directly introduce the notion of the possible in his writings. However, the terms “possible,” “possibility,” or “impossible” in many of their variations were highly used by Bakhtin throughout of his writings. Some, or, maybe, even the most, of these uses were mere functional, reflecting a way of articulating his ideas or a way of talking. However, others apparently represent important philosophical conceptualization, which I want to discuss in this essay.

I have abstracted five distinct philosophical conceptualizations of the notion of “the possible” in Bakhtin's work. The first one is purely negative, “the empty of responsibility possible,” as a form of “theoriticism” criticized by Bakhtin (1993) in his early treatise, tentatively called “Toward a philosophy of the deed [postupok]” by his disciples, which the original beginning, the ending, and the title did not survive. I call his second and third conceptualizations as “the tasked possible” and “the given possible” that Bakhtin (1990) developed as positive concepts in his second early treatise “Author and hero in aesthetic activity.” In his later writings, especially in his book on Dostoevsky (Bakhtin 1999), Bakhtin rethought and criticized the concept of *the given possible* as more negative notion, although he never completely dismissed it and even accepted it as limitedly useful (see Bakhtin 1986), as I will discuss later. At the same time, he introduced the fourth conceptualization of the possible: initially, vaguely, and even negatively for aesthetic as “new possibilities” or unfinalized possibilities (Bakhtin 1990) and then rethought as positive and more defined within his new framework of dialogism in his book on Dostoevsky (Bakhtin 1999). I called this conceptualization “the dialogic possible.” Finally, I sense another conceptualization of the possible in Bakhtin's writing on Dostoevsky – arguably this notion was probably more Dostoevskian than Bakhtinian in its origin. I call this possible “the everything possible” referring to manipulative making the reality according to

one's wishes. Together with Dostoevsky, Bakhtin implicitly criticized this notion.

I will argue that Bakhtin's major contribution to the philosophical conceptualization of the possible is in articulation of *the dialogic possible* and discussing how *the given possible* might contribute to it. I think his secondary contribution was his critique of *the given possible*, *the everything possible*, and *the empty of responsibility possible* as totalizing concepts that ubiquitously emerged in the modernity.

The Empty of Responsibility Possible

In his first treatise, Bakhtin focused on developing philosophy of the responsible deed (*postupok*). The responsible deed actualizes a person's all thoughts, intentions, relationships, and considerations in a unique and final act within a unique context of the world necessities and acts of other people. What makes the deed responsible is that the person accepts and willingly addresses all questions challenging this deed – its intentions, justifications, values, and intended and unintended consequences – raised by others and the self. The responsible deed realizes all subjective and objective hypothetically possible into unique reality, unchangeable any more as things have already happened, for which the person takes responsibility:

The answerable [responsible]. . . deed alone surmounts anything hypothetical, for the answerable [responsible] . . . [deed] is, after all, the actualization of a decision-inescapably, irremediably, and irrevocably. The answerably [responsibly acted out deed] is a final result or summation, an all-round definitive conclusion. The [acted out deed] concentrates, correlates, and resolves within a unitary and unique and, this time, *final context* both the sense and the fact, the universal and the individual, the real and the ideal, for everything enters into the composition of its answerable [responsible] motivation. **The [acted out deed] constitutes a going out once and for all from [the realm of] possibility . . . into [the uniqueness of] what is once-occurrent.** (Bakhtin 1993, pp. 28–29)¹

The emotional-volitional tone, encompassing and permeating once-occurrent being-as-event, is not a passive psychic reaction, but is a certain ought-to-be attitude of consciousness, an attitude that is morally valid and answerably active. This is an answerably conscious movement of consciousness, which **transforms possibility into the actuality of a realized deed (a deed of thinking, of feeling, of desiring, etc.)**. (Bakhtin 1993, p. 37)

Bakhtin refers to a person's subjective and objective hypothetical possible as "an empty possibility" or "a passive possibility," "Any thought that is not correlated with myself as the one who is obligatively unique is merely a passive possibility" (Bakhtin 1993, p. 48). From his point of view, the possible is empty or passive because it does not obligate the person and thus cannot be a subject of a responsibility call. However terrible things a person thought, unless enacted into the obligatory world of the given, necessity, and uniqueness, this thought remains to the empty possibility, for which the person cannot be taken to be responsible. A thought possibility cannot be signed with the person's signature of personal responsibility – only a deed can.

An answerable act or deed is precisely that act which is performed on the basis of an acknowledgment of my obligative (ought-to-be) uniqueness. It is this affirmation of my non-alibi in Being that constitutes the basis of my life being actually and compellingly given *as well as* its being actually and compellingly projected as something yet- to-be-achieved. It is only **my non-alibi in Being that transforms an empty possibility into an actual answerable act or deed** (through an emotional-volitional referral to myself as the one who is active). (Bakhtin 1993, p. 42)

Of course, after the deed is enacted, a past thought possibility shaping this deed becomes a part of the deed, only now, of course, it stopped being just a possibility.

Bakhtin's notion of *the empty of responsibility possible* remains the legal recognition of the freedom of speech in contrast to the freedom of action in democratic societies. In democratic societies, people are exonerated from any legal responsibility for what they say (i.e., *the empty of responsibility possible*) but not for what they act (i.e., deed). Like a thought of a possibility can realize itself in a deed and thus becomes a subject of responsibility

¹ Here and further, in quotes of Bakhtin, the italics are original by the translator, and the bold is mine.

demand, similarly a word can realize itself in a deed and, thus, becomes liable in the face of the law.

Yet, in the treatise that his disciples called “Toward a philosophy of the deed (postupok),” Bakhtin depicted the notion of *the empty of responsibility possible* negatively. The non-obligatory life of *the empty of responsibility possible*, when things may exist or may not exist, is not rooted in anything. It creates an ethical loophole of avoiding any responsibility, an alibi in being. *The empty of responsibility possible* is a part of the irresponsible “theoriticism” that Bakhtin criticized throughout his treatise.

The Tasked Possible and the Given Possible

In his treatise, “Author and Hero in Aesthetic Activity” (1920–1923), which seems to be written in parallel with the treatise “Toward a philosophy of the deed” (1920–1924), Bakhtin had a completely opposite, positive, attitude toward the notion of the possible. This seems to suggest that his notion of *the empty of responsibility possible* should be seen only in the context of his overall inquiry and framework of the responsible deed.

The treatise, “Author and Hero in Aesthetic Activity,” introduced two related other notions of *the possible*, which I called “the tasked possible” and “the given possible.” These notions, rooted in the work of Kant (2004), seemed to be considered outside of Bakhtin’s notions of responsibility and responsible deed and within his discussion of life act and aesthetic act. *The tasked possible* constitutes an inner-subjective ethical emotional-volitional axiological spatial-temporal life horizon for the person.

The “distant homeland” is **located in the axiological spatial-temporal context** of the heroine’s life. It is for her, in her emotional-volitional tone, that **the possible spatial horizon** becomes a homeland: it is a moment in the event of her life. (Bakhtin 1990, p. 213)

The person lives in the world of *the tasked possible* where his/her dreams, goals, aspirations, expectations, envisioned opportunities, perceived risks, and so on constitute the fabric of making deeds

and participating consciousnesses. The inner world of the person is tasked, assigned [zadan, задан] in sense that it is perceived as task to be accomplished. It is future-oriented, the world of the open and unfinalized possible, always pregnant with unfolding and future deeds. With an apparent reference to Kant (see Vladimir Lyapunov’s comment 75 in Russian publication of the treatise in Bakhtin 2003, pp. 575–576), Bakhtin argued that a person is “the condition of possibility” for his/her own life, but a character of a story is seized being such a condition because the possible of the character becomes finalized (i.e., *the given possible*), while the possible of the person remains always unfinalized and open (i.e., *the tasked possible*) (Bakhtin 1990, p. 106).

There are two possible ways of combining the outside world with a human being: **from within a human being-as his horizon [i.e., *the tasked possible*], and from outside him-as his environment [*the given possible*]**. From within me myself [in my horizon], within the meaning-and-value context of my own life, an object *stands over against* me as the object of my own cognitive-ethical and practical) directedness in living my life; in this context, the object is a constituent of the unitary and unique *open* event of being, in which I partake as a participant who has an urgent ‘interest in the outcome of that event. From within my actual participation in the event of being, the outside world is the *horizon* of my active, act-performing [deed-making] consciousness.... The center of gravity in this world is located in the future, in what is desired, in what ought to be, and not in the self-sufficient givenness of an object, in its being-on-hand, *not* in its present, its wholeness, its being-already-realized. My relationship to each object within my horizon is never a consummated relationship; rather, it is a relationship which is imposed on me as a task-to-be-accomplished [assigned], for the event of being, taken as a whole, is an open event; my situation must change at every moment-I cannot tarry and come to rest. The object’s standing over against me, in space and in time, is what constitutes the principle of the *horizon*: objects do not *surround* me (my outer body) in their presently given makeup and their presently given value, but rather-stand *over against* me as the objects of my own cognitive-ethical directedness in living my life within the open, still risk-fraught event of being, whose unity, meaning, and value are not *given* but imposed as a *task* still to be accomplished. (Bakhtin 1990, pp. 97–98)

Bakhtin argued that a person cannot be understood without consummating this *tasked possible*,

constituting this life horizon. Bakhtin argues that comprehension is an aesthetic act of consummation of one's life horizon, so the one's possible becomes given (дан, дан) and finalized. In this aesthetic act, the one's *horizon* becomes his or her *environment*. Consummation is a gift, a surplus of vision, that one person can give another one in which "other-possessed life can always turn into fated life" (Bakhtin 1990, p. 152). The given possible – the juxtaposed, determined, and finalized life possibilities – constitute the fated life.

Fate is individuality, that is, the essential determinateness of a person's existence that determines his entire life, all his acts. In this respect, even the act of thinking is determined not from the standpoint of its theoretical-objective validity, but from the standpoint of individuality – as characteristic precisely for the given determinate person, as predetermined by that person's existence; and **all other possible acts are, likewise, predetermined by individuality or actualize the individuality.** (Bakhtin 1990, p. 175)

In the treatise "Author and Hero in Aesthetic Activity," *the empty of responsibility possible* seemed to become rehabilitated and transformed into *the tasked possible* – a raw material for an aesthetic act of its consummation into *the given possible*. There Bakhtin defined the aesthetics as a transformative relationship between *I* (the spirit, *the tasked possible*) and *the other* (the soul, *the given possible*). In his next big work, the book on Dostoevsky's poetics (1929/1961), Bakhtin again rethought the concept of the possible and seemed to reject either this particular notion of aesthetic as an act of consummation of unfinalized *tasked possible* or the entire notion of aesthetics, apparently dropping this notion from his lexicon.

The Dialogic Possible

In his book on Dostoevsky's poetics, Bakhtin criticized and rejected the given possible – the finalized aesthetic possible – as "a monologic design" in the literature and elsewhere:

In a monologic design, the hero is closed and his semantic boundaries strictly defined: he acts, experiences, thinks, and is conscious within the limits of what he is, that is, within the limits of his image

defined as reality; **he cannot cease to be himself, that is, he cannot exceed the limits of his own character, typicality or temperament** without violating the author's monologic design concerning him. (Bakhtin 1999, p. 52)

At the first glance, Bakhtin returned back to his Kant-inspired notion of *the tasked possible*, which is unfinalized and ethically charged. If in "Author and Hero in Aesthetic Activity" the raw material of the hero's *tasked possible* has to be overcome and transformed into *the given possible* in the aesthetic act of consummation of the hero, in "Problems of Dostoevsky's poetics," this raw material of the tasked, ethically charged, possible seemed to get rehabilitated. However, in my view, this is not accurate. Instead of the apparent rehabilitation of *the tasked possible*, Bakhtin introduced an entirely new concept that I call "the dialogic possible."

The dialogic possible, or what Bakhtin often referred as "the new possible," is born in a human *encounter* with the other, when people are genuinely interested in each other, address each other, and respond to each other taking each other seriously as "a plurality of consciousnesses, with equal rights and each with its own world, combine but are not merged in the unity of the event [co-being]" (Bakhtin 1999, p. 6, italics original). Russian philosopher, psychologist, and educator Alexander Lobok describes Bakhtin's notion of encounter (vstrecha, встреча) in the following way:

The encounter/meeting is the ultimate opportunity to hear yourself in the other. This other can be a physical interlocutor or it can be an encounter with a text or with some phenomenon of culture, which forces me to make that very effort. The encounter/meeting, which I am talking about, is that what presupposes my great effort to encounter the other who is not overlapping with me (i.e., opaque to me), but who is interesting for me. [This meeting generates] a point of puzzlement/surprise and at the same time it is a point of some kind of unusual joy of discovery of myself in the [other] unexpected for me. This is as if [the other] talks about something that is deeply intuitively clear to me. And at the same time, [the other] creates the [new] space, in which these deep intuitions of mine begin to live and begin the fireworks of my own creative thinking . . . [The other] capture[s]/hook[s] something in me, which is essential about me. To "capture/hook" something in me, means to provoke, spark, self-actualize, and initiate some kind of my own activity.

And this situation of the encounter/meeting that I am describing here is, as a matter of fact, an educational situation. The genuine education unavoidably involves an element of provocation.

What is important for me, as a teacher, is that my encounter with the students is the [new] space of my own personal self-growth, my own self-actualization. The encounter with my students is the process of my own self-making/self-creation/self-becoming and, thus, my own self-education. (Lobok 2014; the fragments are from two video conferences, transcribed and translated by us). (Cited in Matusov and Marjanovic-Shane 2015, p. 216)

In the dialogic encounter, new possibilities for person's self-actualization, new horizon, new worldview, and new assigned possibility emerge. Although the most acute encounter that generates the dialogic possible often occurs in physical face-to-face meeting, it can also occur via a text and even via one's imagination, when a person involves in an imaginary dialogue with real past people or even with imaginary literary characters. The last possibility was described by infamous Russian political terrorist Boris Savinkov² (1879–1925) in his diaries (Savinkov and Shaplen 1931), where the real political terrorist Boris Savinkov argued with fictitious literary characters of Leo Tolstoy (Pierre Bezukhov, *War and Peace*) and of Fyodor Dostoevsky (Rodion Raskol'nikov, *Crime and Punishment*) about ethical issues of political terrorism. Bakhtin highly appreciated the literary artistic work by Dostoevsky for the creation of the Big Encounter and, thus, Big Dialogue:

As an artist, Dostoevsky uncovered in the image of a given idea not only the historically actual features available in the prototype (in Napoleon III's *Histoire de Jules Cesar*; for example), but also its *potentialities*, and precisely this potential is of the utmost importance for the artistic image. As an artist Dostoevsky often divined how a given idea would develop and function under certain changed conditions, what unexpected directions it would take in its further development and transformation. To this end, Dostoevsky placed the idea on the borderline of dialogically intersecting consciousnesses. He brought together ideas and worldviews, which in real life were absolutely estranged and deaf to one another, and forced them to quarrel. He extended, as it were, these distantly separated ideas by means of a

dotted line to the point of their dialogic intersection. In so doing he anticipated future dialogic encounters between ideas which in his time were still dissociated. He foresaw new linkages of ideas, the emergence of new voice-ideas and changes in the arrangement of all the voice-ideas in the worldwide dialogue. And thus the Russian, and worldwide, dialogue that resounds in Dostoevsky's novels with voice-ideas already living and just being born, voice-ideas open-ended and fraught with **new possibilities**, continues to draw into its lofty and tragic game the minds and voices of Dostoevsky's readers, up to the present day.

In such a way, without losing any of their full and essential semantic validity, **the idea-prototypes used in Dostoevsky's novels change the form of their existence: they become thoroughly dialogized images of ideas not finalized monologically; that is, they enter into what is for them a new realm of existence, artistic existence.** (Bakhtin 1999, p. 91)

I argue that Bakhtin's notion of the dialogic possible is super important for humanistic and social sciences. Bakhtin essentially introduced a dualism in social sciences by insisting that human subjectivity can be studied both as *the given possibility*, depicting human subjectivity as the finalized and objective, and as *the dialogic possibility*, addressing and responding to the studied other. The objective subjectivity, rooted in the necessities of the given, is studied by the modern positivist sciences (Matusov et al. 2019a). However, the authorial subjectivity, rooted in a dialogic encounter, should be studied only in a dialogue science. Bakhtin insisted that the very category of necessity is essentially inhuman, while humanness is found in the striving to liberate oneself from necessity: "[The concept of] 'necessity' is an 'inhuman' category, according to Bakhtin" (commentary by Gogotishvili in Bakhtin 2002, p. 622; translated by me). My colleagues and I argue "that dialogic analysis belongs to dialogic science, which focuses on studying 'the surplus of humanness' (Bakhtin 1991, p. 37). 'The surplus of humanness' is 'a leftover' from the biologically, socially, culturally, and psychologically given – the typical and general – in the human nature. It is about the human authorship of the ever-unique meaning-making" (Matusov et al. 2019b, p. E20). "...in Dostoevsky man [person] transcends his 'thingness' and becomes the 'man in man'".

²https://en.wikipedia.org/wiki/Boris_Savinkov

only by entering the pure and unfinalized realm of the idea, that is, only after he has become an unselfish man of the idea. Such are all the major heroes in Dostoevsky—that is, those who participate in the great dialogue” (Bakhtin 1999, p. 86).

Bakhtin argued that the objective subjectivity – the human subjectivity that is predictable, common, stable, and calculatable – studied by the positivist science becomes legitimate only when it is dialogized, when it returns to the authorial consciousness of the studied person, and when it is addressed and responded by the authorial consciousness of the researcher. Bakhtin noticed that all characters in Dostoevsky’s polyphonic novels and stories know everything that other people think and tell about them (Bakhtin 1999, pp. 52–53, 72). When the person’s subjectivity is objectivized behind his/her back, this truth about the person becomes oppressive.

A man [person] never coincides with himself. One cannot apply to him the formula of identity $A \equiv A$. In Dostoevsky’s artistic thinking, the genuine life of the personality takes place at the point of non-coincidence between a man and himself, at his point of departure beyond the limits of all that he is as a material being, a being that can be spied on, defined, predicted apart from its own will, “at second hand.” The genuine life of the personality is made available only through a *dialogic* penetration of that personality, during which it freely and reciprocally reveals itself.

The truth about a man in the mouths of others, not directed to him dialogically and therefore a *secondhand* truth, becomes a lie degrading and deadening him, if it touches upon his “holy of holies,” that is, “the man in man.” (Bakhtin 1999, p. 59)

To study a person means to understand him or her in a dialogic encounter, Bakhtin argued that understanding involves a researcher’s authorial evaluation and authorial judgment of the studied person’s ideas addressing this person and the readers of the research in a dialogue encounter, “Evaluation as a necessary aspect of dialogic cognition” (Bakhtin 1999, p. 161). The social science researcher is always an author in a dialogue. The researcher authors his or her evaluations and judgments. These evaluations and judgments can be even unpleasant and disagreeable constituting dramatic events in dialogic encounters – they can constitute

dialogue-agreement, dialogue-admiration, dialogue-disagreement, and/or dialogue-protest (Kurganov 2009; Matusov et al. 2019a, b). “Human thought is not systematic but dialogic. Human thought demands a response, objections; it demands an agreement or a disagreement. Only in the atmosphere of this free struggle, the human and artistic thought can develop itself” (Bakhtin 2002, p. 459; translated by me).

Understanding and evaluation. **Understanding is impossible without evaluation.** Understanding cannot be separated from evaluation: they are simultaneous and constitute a unified integral act. The person who understands approaches the work with his own already formed worldview, from his own viewpoint, from his own position. These positions determine his evaluation to a certain degree, but they themselves do not always stay the same. They are influenced by the artwork, which always introduces something new. Only when the position is dogmatically inert is there nothing new revealed in the work (the dogmatist gains nothing; he cannot be enriched). The person who understands must not reject the possibility of changing or even abandoning his already prepared viewpoints and positions. In the act of understanding, a struggle occurs that results in mutual change and enrichment.

A meeting [encounter] with a great human being, as something that determines, obligates, and unites – this is the highest moment of understanding. (Bakhtin 1999, p. 142)

In my authorial judgment, addressing the readers, Bakhtin’s notion of *the dialogic possible* does not reject his prior notions of *the tasked possible* and *the given possible*,² but rather it calls for dialogization of these prior notions. *The given possible* – the objective subjectivity, the environment of the studied person seen by the researcher through the researcher’s surplus of vision, and the authorial judgments by the researchers about the studied person – must be offered by the researcher to the researched and other as provocations for a dialogue. As Alexander Lobok points out, this dialogic encounter opens new possibilities for the person’s self-actualization – *the tasked possible*. “We could say that in Dostoevsky man [person] transcends his ‘thingness’ and becomes the ‘man in man’ only by entering the pure and unfinalized realm of the idea, that is, only after he has become an unselfish man of the idea. Such

are all the major heroes in Dostoevsky – that is, those who participate in the great dialogue” (Bakhtin 1999, p. 86).

The Everything Possible

Finally, I want to briefly introduce another notion of the possible that I abstracted from Bakhtin again with the reference to work by Dostoevsky – *the everything possible*. Originally, this notion was introduced by Dostoevsky in the novel *The brothers Karamazov* by Ivan Karamazov arguing that if God does not exist, “everything is permitted.” However, Bakhtin traces this idea throughout Dostoevsky’s work:

Very many, and including the most important, ideas, themes and images of [Dostoevsky’s] work... appear here in extremely keen and naked form: the idea that “**everything is permitted**” if there is no God and no immortality for the soul (one of the leading idea-images of his work); the related theme of **confession without repentance and of “shameless truth,”** which runs through all of Dostoevsky’s work beginning with *Notes from Underground*; the theme of the final moments of consciousness (connected in other works with the themes of capital punishment and suicide); the theme of a consciousness on the brink of insanity; the theme of sensuality, penetrating the highest spheres of consciousness and thought; the theme of the total “inappropriateness” and “unseemliness” of life cut off from its folk roots and from the people’s faith, and so on—all these themes and ideas, in condensed and naked form, are fitted into the seemingly narrow confines of this story. (Bakhtin 1999, p. 144)

Abstracting from theological debates about the existence of God and immortality of the soul as the basis of morality – i.e., ethical self-limitation in the relationship with others – this Dostoevsky-Bakhtin notion of *the everything possible* resonates with the current post-truth and post-morality political currents. In the post-truth, post-morality world of the everything possible, there are no judges – only the power-win rules. The might, the manipulative, the cunning is the right. “If I can, I must. If I cannot, I must double my efforts.” The other is shamelessly rejected together with dialogue and responsibility. Thus, only irresponsible deed is possible. *The everything possible* is a form of *the empty of responsibility possible*.

The Possible in the Life and Work of René Magritte

Lisa Lipinski

Columbian College of Arts and Sciences, George Washington University, Washington, DC, USA

Abstract

René Magritte (1898–1967) was an internationally renowned painter, draughtsman, printmaker, sculptor, photographer, filmmaker, and the leading figure in the Belgian Surrealist movement. Using all of the pictorial techniques of oil painting at his disposal, Magritte took ordinary and banal objects we see in the world and put them into paintings, which visualize not what is real, but what is surreal, the resolution of the dream and waking state, in order to invoke a state that he called mystery. He envisioned multiple possibilities in creating an image rather than confining himself to the binary opposition of logical and illogical juxtaposition. He was interested in the problems posed by painting as a visual and philosophical art form. For Magritte, painting was a form of thinking and rather than replicating reality, he made painting into an art of the possible.

Research on Magritte

René Magritte (1898–1967) may be the most famous surrealist in the world today. His iconic imagery has been imitated, appropriated, and *détourned* in all manner of cultural products, from high art to popular culture, which is fitting considering that he began his career as a commercial artist designing advertisements and for a time in the 1930s, he operated his own graphic design studio. In *Ceci n'est pas un Magritte. Essay sur*

Magritte et la publicité Georges Roque examined the semiotics of Magritte's advertisements, showing the formal and conceptual links between his graphic designs and his paintings (Roque 1983).

Magritte's paintings continue to enchant successive generations of spectators who flock to contemporary exhibitions around the world and the Magritte Museum, which opened in Brussels in 2009. To accompany the opening of the museum, Michel Draguet wrote a new biography of the artist, adding details related to his early life in Charleroi and Brussels (Draguet 2014). Recent exhibitions provided opportunities to view his best-known works and to rediscover what makes his art so compelling and critically important to the history of modern art. A major retrospective at the Museum of Modern Art, New York, *Magritte: The Mystery of the Ordinary, 1926–1938* (Umland et al. 2013) brought together about 80 paintings, collages, and objects with a selection of photographs, periodicals, and early commercial work, tracing central themes from this formative period of his career. At the San Francisco Museum of Modern Art, the exhibition *René Magritte: The Fifth Season* (Haskell 2018) was organized around the museum's notable painting, *Personal Values*, acquired in 1998. The exhibition included the complete series, *The Empire of Light*, in which an illuminated sky appears above a neighborhood at night, and select examples from the sunlit or *Vâche* periods, which are less well-known and have been considered marginal to his oeuvre. In Paris and Frankfurt, the exhibition *Magritte. The Treachery of Images* (Ottinger 2017) brought together iconic and lesser known works. The catalog essays showed that Magritte's surreal images were not the result of chance or the dream, but his exploration of the traditions and concepts of painting and philosophy. The catalog reproduced correspondence between Magritte and prominent philosophers, Chaim Perelman, Alphonse De Waelhens, and Michel Foucault. *Magritte and Contemporary Art: The Treachery of Images*, an exhibition at the Los Angeles County Museum of Art (Magritte et al. 2006) revealed the precise connections between Magritte's work and major contemporary artists. Magritte's art was admired in the later years of his life, and continues to be

popular with artists, art historians, and the general public.

Magritte's friends and colleagues began publishing accounts of his life and career, starting in 1943, with Marcel Mariën's monograph (Mariën 1943), *Magritte*, followed by Louis Scutenaire's 1947 monograph *René Magritte*, and Patrick Waldberg's *René Magritte*, published in 1965 (Waldberg 1965). The American art historian Suzi Gablik met the artist in 1959 and lived with him and his wife Georgette for 8 months gathering information. Gablik published *Magritte* in Great Britain in 1970 (1972 in America), reissued in 1985. (Gablik 1985) A.M. Hammacher's *Magritte* was published in 1974. Harry Torczyner's *René Magritte: The True Art of Painting* (Torczyner 1985) drew on his long-standing friendship with the artist and published some of Magritte's writings. In 1969, British art critic and historian David Sylvester curated a retrospective for the Tate Gallery (Sylvester 1969), which he followed with a monograph *René Magritte and the Silence of the World* in 1992 (Sylvester 1992). With Sarah Whitfield and Michael Raeburn, Sylvester wrote and edited the comprehensive five-volume *René Magritte, catalogue raisonné* (Sylvester et al. 1992a, b, 1993). A sixth volume of *Newly Discovered Works* was published in 2012 (Whitfield 2012).

Recent critical monographs provide new insights into Magritte's biography and offer fresh interpretations of Magritte's art. In *René Magritte: Beyond Painting* (Allmer 2009) Patricia Allmer employed a wide range of literary and philosophical theoretical frameworks to analyze the paintings, noting the intertextual relations between Magritte's work and that of other Surrealist artists (see entry ► "Surrealism"). Her latest book *René Magritte* (Allmer 2019) noted the significance of popular entertainments on his art, specifically the circus and county fairs in Charleroi, magic shows, popular cinema, and detective fiction. In *Decoding Magritte* (Levy 2015) Silvano Levy applied Roman Jakobson's linguistic theories of metaphor and metonymy and the neurological disorder of aphasia to decode the hidden structures of Magritte's paintings. The inclusion of previously unavailable source material in the

form of photographs and substantial interviews with Georgette Magritte, Louis Scutenaire, Irène Hamoir, Marcel Mariën, and George Melly provides valuable primary resources. The more anonymous his pose as the man in the bowler hat, ironically the more subject-like and subjective his work appears to be, in both his self-portraits and in photographs of him and his work. Exploring Magritte through the lens of contemporary art theory, including the idea of painting as indexical, allows a new, non-iconic view of his art to emerge in *René Magritte and the Art of Thinking* (Lipinski 2019).

Magritte produced a voluminous amount of writing in the form of letters, catalog essays, brief texts on art, autobiographical statements, and interviews. For primary sources, indispensable books are André Blavier's edited *Écrits complets* (Magritte 1979) and Kathleen Rooney and Eric Plattner's edited English translation of *Selected Writings* (Magritte 2016).

A Disturbing Poetic Effect

After his studies at the École des Beaux-Arts in Brussels between 1916 and 1918, Magritte quickly aligned himself with the Belgian avant-garde, who were debating self-reflexive ideas about the nature of art. In the summer or fall of 1923, Belgian writer Marcel Lecomte, a member of the Belgian surrealist movement, showed Magritte a reproduction of Giorgio de Chirico's *Le chant d'amour* (*The Song of Love*), 1914. Until then, Magritte had experimented with different styles of artistic expression, including cubism, futurism, and abstraction. After de Chirico's revelation, Magritte saw new possibilities for painting. Through distortion of scale and perspective, using traditional techniques of painting, such as chiaroscuro, De Chirico transformed ordinary volumetric objects into scenes with the power to induce a deeply felt and existential sensation. No longer a window onto the real world, nor an abstraction, painting was a dreamlike and enigmatic expression of the depths of the human mind. Magritte recalled what moved him about this painting: "This triumphant poetry supplanted the

stereotyped effect of traditional painting. It is a complete break with the intellectual habits peculiar to artists who are prisoners of their talent, virtuosity and all petty aesthetic frills. It is a question of a new vision in which the viewer rediscovers his isolation and hears the silence of the world.” (Magritte 2016, p. 59).

As he noted in his autobiography, from 1925 to 1936 Magritte sought to create “a disturbing poetic effect” in his paintings and he did so by taking objects out of their usual settings and relocating them to new places and placing them in unexpected combinations. He also created new objects, changing the substance, for example, painting a sky made of wood, using words with images, and modifying images from commercial art as well as the Larousse dictionary. When recontextualized, known objects can gain affective power, and vaguely familiar objects can become new. Magritte’s paintings manifest the surreal or surreality, that is, the resolution of the dream and waking state, in order to invoke a state that he called mystery.

In addition to painting objects, both real and invented, Magritte added curtains, frames, and mirrors, which are all traditional metapictorial devices, to enhance the illusion of three dimensions and add to the complexity of the pictorial space (Fig. 1). *La rencontre* (*The Encounter*), 1926. [Oil on canvas, 139.5 × 99 cm. Kunstsammlung Nordrhein-Westfalen, Düsseldorf. Banque d’Images, ADAGP/Art Resource, NY. © 2017 C. Herscovici/Artists Rights Society (ARS), New York] depicts a blue curtain drawn back to reveal three bilboquet figures, one of his iconic objects taken from a children’s game, which appear to confront their own images in a mirror. The space is ambiguous, neither stage set nor landscape, and much of what one sees is the reflection and the complex perspective of the frame. The mirror is set at an angle to the picture plane. The top edge is not parallel to the bottom, where a barely perceptible line marks the boundary between the actual scene and its reflection. Dark mountains rise up behind the bilboquets under a cloudy gray sky. Two contradictory levels of pictorial reality are on display: the sky appears in the reflection as well as above and behind the mirror. Part of the mirror frame is cut off at the right edge

of the painting, and behind it, pushed tight as if supporting the mirror, is another wooden frame. The viewer is positioned slightly above the human surrogates, whose lower contours are cut off. The chiaroscuro and the shadows on the ground give the objects a sense of solidity and weight. A light source flows in from the left on the other side of the curtain. As can be seen only in the reflection, the terrace ends abruptly behind the curtain and another gray area floats adjacent to it. There is no visible wall behind the figures, which are in our implied space. The space depicted, then, exists behind the viewer, who is therefore obliterated in the reflection. The painting visualizes the complexity of vision as theorized by the French psychoanalyst Jacques Lacan and Maurice Merleau-Ponty. The eyes of the three figures are not properly aligned with those of their doppelgängers, which creates the uncanny feeling that

The Possible in the Life and Work of René Magritte,
Fig. 1 *La rencontre* (*The Encounter*), 1926. [Oil on canvas, 139.5 × 99 cm. Kunstsammlung Nordrhein-Westfalen, Düsseldorf. Banque d’Images, ADAGP/Art Resource, NY. © 2017 C. Herscovici/Artists Rights Society (ARS), New York]

they are looking elsewhere and at something besides their own reflection, namely, the viewer. (Lipinski, 23) The field of vision has two sides, one from which we see and another from which we are seen. In *The False Mirror*, 1929, a single human eye returns our gaze, holding the viewer enthralled in its mystery. The dark oval of the pupil floats in the middle of the iris, which is composed of a cloud-filled blue sky.

Magritte and his wife Georgette lived in Paris from late 1927 to 1930, during which time he painted many of his most famous works, including *The Treachery of Images*. He wrote to Paul Nougé: “I think I have made a really striking discovery in painting . . . as a result of the experiments I’ve made here, I have found a new potential in things—their ability to become gradually something else, an object merging into an object other than itself” (Sylvester 1992, p. 246). Magritte experimented with this new technique of metamorphosis, or becoming, with landscapes and figures (Fig. 2). *Découverte (Discovery)*, 1927. [Oil on canvas, 65 × 50 cm. Royal Museums of Fine Arts of Belgium, Brussels. Banque d’Images, ADAGP/Art Resource, NY. © 2017 C. Herscovici/Artists Rights Society (ARS), New York] represents a woman whose flesh appears to be composed of another substance, either wood or the fur of an animal. Before our eyes, she appears to be in the process of becoming another kind of being or substance. For Magritte, painting does not express emotion or feelings, which he believed have no visible form. In a statement written for an exhibition in 1960, Magritte wrote: “Resemblance is part of the essential mental process; that of resembling. Thought ‘resembles’ by becoming what the world presents to it, and by restoring what it has been offered to the mystery without which there would be no possibility of either world or thought. Inspiration is the result of the emergence of resemblance” (Magritte 1960). Thought is no longer limited to the recognition of what is, but extends to what something could become, to its power and potential (see entry ► “Thought Experiments”).

Magritte’s paintings with words and images offer compelling lessons about the nature of pictorial representation and the power of images to

deceive, to puzzle, to make us see things we overlook, and, ultimately, to make us think about what is possible. The artist placed words and forms in various configurations and combinations in order to explore the image’s inherent communicative capacity, connecting the issue of resemblance to thought, and to feeling, in an original way. In *La trahison des images (The Treachery of Images)*, 1929) a tobacco pipe floats in a pale off-white space, its shiny brown bowl and curvaceous stem reflecting the light. Below the pipe, a neat cursive script reads *Ceci n’est pas une pipe*, informing the viewer that this object is not a real pipe – it is an image of a pipe. No other painting by him has generated as much interest and interpretation. (Foucault 1983) *The Treachery of Images* represents the culmination of Magritte’s word paintings. He would produce more paintings with words, but this one succinctly expresses two important ideas. One, the obvious statement that

The Possible in the Life and Work of René Magritte, Fig. 2 *Découverte (Discovery)*, 1927. [Oil on canvas, 65 × 50 cm. Royal Museums of Fine Arts of Belgium, Brussels. Banque d’Images, ADAGP/Art Resource, NY. © 2017 C. Herscovici/Artists Rights Society (ARS), New York

this is a painting of a pipe, not a real pipe. The second, the demonstration that the power of resemblance, defined as “thought” by Magritte, overrides all other processes of signification, and constitutes the most powerful mode of thinking. The potential of the forceful images he produced in this period extend to the realms of the affective, psychological, economic, and aesthetic. Such is the treachery of images – they produce truth even as they have the ability to misrepresent it.

Magritte’s art forces us to think above and beyond the simple process of recognition. This is a pipe, one says when looking at a painting of an object that resembles a pipe. This painting of a pipe is not a pipe. This painting of a pipe mounted inside a painting is not a pipe. Through a range of pictorial devices, like words and paintings-within-paintings as well as images of floating rocks, Magritte asserts the phantasmatic power of the false, the operation of the simulacrum. Levitating objects defy gravity in reality, but in painting they embody a different mode of thought, not of resemblance, which is a way copies are judged according to their relation to a model or the idea, but of difference.

In his 1929 pictorial essay, Magritte wrote: “No object is so tied to its name that we cannot find another one that suits it better” (Magritte 2016, p. 33). The drawing above the statement shows a leaf with a line connecting it to the inscription *Le canon*. The label does not match the object. Throughout the essay, Magritte considers the permutations of the elusive relationship between drawn objects, their names, and reality. This statement illustrates the central idea of structuralism – namely, the arbitrary nature of the linguistic sign (see entry “► Semiotics”). If any word can replace another, then there is no ground, no foundation on which to base a shared cultural heritage or understanding. At the same time, Magritte’s lesson opens up possibilities for change and evolution in our uses of words and images. The relationship between words and images, between poetry and painting, has a long history in the study of the visual and literary arts and in theories of rhetoric, communication, and knowledge. Through his investigation of both the iconic and linguistic lexicons, Magritte placed

himself in this tradition, seeking to counteract the sedimentations, beliefs, and unconscious rigidity of the mental habits developed around reading and looking at art.

The word paintings open up poetic potentialities of things as well as words. In a modified version of a public lecture, “La Ligne de vie,” given by Magritte in 1938 at the Koninklijk Museum van Schoone Kunsten, Antwerp, first published in 1947 in a monograph on Magritte by Louis Scutenaire, Magritte explained how art can transcend the limitations of ordinary language.

“The habit of speaking for the immediate needs of life imposes a limited meaning on words that denote objects. It seems that ordinary language sets imaginary boundaries to imagination.

But one can create new relationships between words and objects and specify qualities of language and objects of which we are generally unaware in the course of daily life.” (Blavier and Magritte, 1979, p. 120).

Visible things can hide other things, thereby opening up possibilities beyond one’s immediate perception. Magritte experimented with the picture-within-a-picture to produce a number of resonant images, such as *La condition humaine*, 1933 (Fig. 3), an important painting in his oeuvre, constituting a veritable treatise on the nature of painting, vision, and thought. [*La condition humaine* (*The Human Condition*), 1933. Oil on canvas, 100 × 81 cm. The National Gallery of Art, Washington, DC. Gift of the Collector’s Committee. © 2017 C. Herscovici/Artists Rights Society (ARS), New York]. Initially, we have the impression of looking at a painting of a window. As we look more closely, we see the three legs of an easel supporting a canvas – a line of tacks runs along its right edge, and it overlaps the curtain to the left. The painting-within-a-painting appears to come forward into “our” space, though it is our space only within the fictive terms of the painting. It may require some effort to realize the possibility that the view through the window may be different from the landscape painting. Because the window frame and painting are set at a slight angle to the picture plane of the real painting, allowing for the continuation of the lines of the landscape, we are led to assume that the image on the easel and

The Possible in the Life and Work of René Magritte, Fig. 3 *La condition humaine* (The Human Condition), 1933. Oil on canvas, 100 × 81 cm. The National Gallery of Art, Washington, DC. Gift of the Collector's Committee. © 2017 C. Herscovici/Artists Rights Society (ARS), New York

the view through the window are one and the same. But we will never know. There is no way to verify the truth of what we see, or think we see. Edges keep things apart, while illusionist space holds them together. By seeming to abolish the difference between the painting-within-the-painting and the “real” painting, Magritte makes it all the more obvious, just as he makes us aware that illusionism depends on the most artificial and aesthetic conditions, specifically observing the separateness of pictorial space from real space, created by the painter as well as by the mind of the viewer (see entry ► “[Illusion in Art](#)”).

Magritte and Surrealism

Magritte’s art presents a paradox; while its unconventionality was consistent with surrealist goals of revolt and liberation, his conceptual approach diverged from that of his French surrealist peers. Magritte’s images did not come from dreams, nor

did he practice automatic writing or drawing. His methods were deliberate, systematic, and exacting, in his search for the mysterious image of what was possible in painting. Magritte painted things realistically enough to deceive, but not in order to perform the passing treachery, playful or otherwise, associated with *trompe l’oeil*. The purpose of his deception, rather, was to evoke persistent “mystery,” a quality that for Magritte carried no religious or metaphysical connotation. He used *trompe l’oeil* to add another layer of depth, related to reflexivity, to show the virtual within the actual, to make something that was possible but not yet visible appear as full and present in the image. Thus, there had to be some connection with reality. He wanted the viewer to stay with the inspired image of his thought, which involved initially the search for hidden affinities between two things and later the creation of affinities generated by his thoughts about the things themselves. For Magritte, resemblance operates on two levels: first, by isolating images the world offers, such as the things he lists, and second, by making those images of likeness (thought) visible through the application of paint. “An unknown image from the shadows is called forth by an image known in the light” (Magritte 2016, p. 211).

In an interview with Jan Walravens, Magritte explains the relationship of the surreal, reality, and mystery: “The surreal is reality which has not been separated from its mystery. The surrealist painter describes thought which can be made visible through painting. This thought evokes mystery, the mystery without which no thought nor world would be possible.” (Magritte 2016, p. 200) Reality was not an ordinary phenomenon for Magritte, but something deeply mysterious and complex, never fully knowable. In *Le séducteur* (*The Seducer*, 1950) a ship whose entire form, both the schooner and the sails, appears to be composed of water floats on a calm sea. Animated brushwork merges the vessel with the sea and draws attention to the painting’s surface, making it into something other than what it depicts. Resemblance takes over the world, seen in places where there is some kind of contiguity, even as the image could not possibly exist in reality (see entry ► “[Possible in Visual Arts](#)”).

In the spring of 1943, Magritte changed his signature style, discarding his meticulous illusionism in favor of the palette and painterly technique of the French Impressionist, Pierre-Auguste Renoir. He sought to dispel the gloom and pessimism of the war years with a kind of painting which would bring joy and pleasure. In defense of his new style and in response to the Surrealists who criticized his new works, Magritte wrote five separate manifestos between August 1946 and September 1947, in which he noted that painting objects, both real and imaginary, with bright, pastel colors in the full light of the sun, has the power to charm and “to counteract this depressing, banal habit” (Magritte 2016, p. 92). In advocating for “Surrealism in the Sunshine,” he argues that surrealism must no longer be “a bridge between the two wars” (Magritte 2016, p. 97). He believed that one had to move forward rather than dwelling on the past, and to find new ways to use the tools of painting to make an art for the future. Magritte remained in Brussels throughout the war and afterward, with brief trips abroad to attend openings of his exhibitions. In 1948, he signed a contract with the art dealer, Alexandre Iolas, who remained his agent until his death on 15 August 1967.

Late in his life, when asked whether Surrealism was a doctrine or a permanent attitude, Magritte replied that it was “[a]n attitude that exists today, and that has existed for ever . . . In brief, Surrealism is the appearance of a possibility as yet unknown to the mind. I don’t see why the mind couldn’t manifest again this possibility, which is the opposite of a habitual way of thinking” (Magritte 2016, p. 216). His critical and popular reputation grew in the 1960s, and, with greater exposure through exhibitions and monographs, his art exerted a critical influence on a new generation of artists in Europe and the United States.

Conclusion

Magritte constructed his own myth of the bourgeois painter or “secret agent” in and through painting. As we look at the images in Magritte’s paintings, our thoughts, perceptions, and

reactions are set in motion. Though none of us can escape language, Magritte found a way to offer a glimpse of something beyond words, what he would call an image of resemblance. Throughout his career, he developed a repertory of ordinary objects, altering them through techniques he devised in Paris in the 1920s, from trompe l’oeil to collage, metamorphosis, scale shift, and recontextualization. His objective was to access the unknown, to create a kind of spiritualized painting, an art for the present and the future, that is, an art of potentiality. Through painting, his labor, he sought to maximize the power of art to produce new and previously unimagined and unlimited thoughts. In Magritte’s hands, painting could be used to shock, shatter, and provoke experience, to transform life.

The Possible in the Life and Work of Walt Disney

Margaret McVeigh
Griffith Film School, Griffith University,
Brisbane, QLD, Australia

Abstract

Walt Disney (1901–1966) is one of history’s most dynamic examples of a man who dreamed the impossible and made it possible. He was both a business and creative entrepreneur who has had an everlasting impact on twentieth century animation, entertainment, and culture. There are a number of important biographies of Walt Disney the man which trace his journey to realize his dreams from his start in life as an American Midwestern farm boy, to a pioneering animation artist and

filmmaker, to a founder of the global phenomena which commenced as a small two-man animation studio the Walt Disney Company, to become one of the most powerful international multimedia entertainment conglomerates in today’s world.

Disney made his mark as an innovative storyteller in films such as *Steamboat Willie*, *Snow White and the Seven Dwarfs*, and *Fantasia*. In all that he did he managed to break new ground and create new possibilities in the creation of fantasy worlds by bringing together new genres in screen-based storytelling, new technologies, and new visions for destination based entertainment via the concept of Disneyland.

This entry draws upon key biographical work and articles written about Disney to collate insights into the driving force of his work as an artist and entrepreneur – the ability to dream big visions, to trust in himself and his abilities, to surround himself with like-minded people who would support his dreams, and to go into uncharted territories to create a world of entertainment drawn from the creative imagination of one man. When Disney died on December 15, 1966, he held the record for a film producer with the most Academy Awards earned by an individual, having won 22 Oscars from 59 nominations.

This entry will deal with the work of the “Classic Walt” – roughly the work conceived by Walt Disney as the founding father of The Walt Disney Company from 1923 to 1966 and will draw extensively from the writing and words of Walt Disney the man himself as reported in archives used in key biographical work.

Keywords

Walt Disney · Disney brothers · The Walt Disney Company · Disneyland · *Snow White and the Seven Dwarfs* · *Fantasia*

Disney the Dreamer

Walter Elias Disney was attracted to the world of make-believe and fantasy. He loved to draw and took art classes as a boy. His first job was at the

Film Ad Company which produced animated ads to show between films in the cinema. In his work at Film Ad, Disney demonstrated what would become a lifelong trait – he advanced his knowledge of what was possible in animation by working out “tricks that they hadn’t done” (Barrier 2007, p. 27). Following this, he briefly worked in advertising then opened his own studio in his garage to produce short animations called Laugh-O-Grams. In the early 1920s, he and his brother, Roy O. Disney, went to Los Angeles to create Disney Brothers Studio (Wawro in Wise 2014, p. 152) which eventually became The Walt Disney Company. In 1928, Walt had his first stand out success with the development of the character of Mickey Mouse. Disney was the voice of Mickey Mouse until 1947.

The Disney brothers broke the bounds of the possible when they made *Steamboat Willy* (1928), the first animated short feature with synchronized sound. In 1933, Disney produced *The Three Little Pigs* for which he won an Academy Award. Critics have cited this film as creating a breakthrough in character animation. In making this film, Disney realized the importance of telling emotionally engaging stories to connect with audiences. It is also regarded as one of the industry’s most successful short animations with its “wildly positive audience responses to the film, its extensive run in the cinemas, its promotion often above the feature film of the day, its widespread cross-promotional success (sheet music sales, dolls of the pigs and wolf, etc.), and its extensive international distribution” (Danks 2003, np).

In the 1930s the Disney brothers turned to producing feature length animated films and they began the four-year production of the film *Snow White and the Seven Dwarfs* (1937) based on the Brothers Grimm fairy tale of the same name. This Disney’s first full-length animated feature was labeled “Disney’s folly” because of studio cost overruns but it went on to become the highest grossing film of 1938 and Disney was awarded an Oscar for the film (Nugent in Mollet 2013, p. 109).

The importance of *Snow White and the Seven Dwarfs* as an example of Disney’s ability to turn, what some would say are impossible dreams into

reality, cannot be underestimated. Likewise, the importance of Disney’s belief in the power of fantasy in day-to-day life as told via the story of this film can also not be underestimated. *Snow White and the Seven Dwarfs* was released following the period of the Great Depression in America. Americans had lost their vision of the American Dream developed in the early 1920s and were suffering poverty, unemployment, and economic oppression. Using the power of animation, Disney was able to create a vision of a better world for his audience. Mollet argues that through his fantasy movies like *Snow White*, that “Disney kept the dream of success alive through *Snow White*’s ability to dream. She sings of her wish to find the one she loves and for him to take her away from her current plight. The prince appears, and the two sing together of the joys of finding their love” (Mollet 2013, p. 114).

Scholars see Disney’s adaptation of classical European fairy tales as a seminal influence on American culture and the American psyche in the Twentieth Century. Mollet argues that because of his own childhood suffering with a tyrannical father, that Disney was attracted to a world of world of make-believe and fantasy. “He felt drawn to fairy tales and the ideal of a ‘happily ever after’ through the struggles he had undergone in his own life” (2013, pp. 113–114).

One can thus interrogate how Disney used the fairy tale to enter a world of the possible. Mollet considers the key arguments in this debate noting Zipes’ assertion that Disney “cast a spell” over the classical fairy tale, capitalizing on American naïveté to infuse his viewers with false hope (Zipes in Mollet 2013, p. 111), whereas Sammond argues that “Disney was represented as an interceding between an ideal past and an unrealized ideal future, distilling the best impulses of that past into a digestible form that would reappear as the present corrected in that future” (Sammond in Mollet 2013, p. 110).

Disney Firsts

While *Snow White and the Seven Dwarfs* created a new and more positive story spin on the original

Brothers Grimm fairy tale, the film showcased Disney's daring to enter the realm of the possible. He saw cartoons not just as an adjunct to the main feature film screening but as an art form in their own right. *Snow White and the Seven Dwarfs* was made at a then-staggering cost of \$1.5-million and it also created new ways of using technology to tell screen based stories. Disney used the then new medium of sound to be one of the first to use song to tell his stories, rather than only as an emotional accent to the action. He also was the first in Hollywood to use Technicolor in animation. His use of color "added life and character to the story, making it a more poignant and utopian representation of America in the 1930's than many movies of the time. The bright colours of Disney's animation reflect the optimism of the story and hence ultimately the story's underlying ideology" (Mollett 2012, p. 122). *Snow White* was also a stellar leap not only in running time but also in technical artistry and vision. New depth was added to traditional 2D action with the use of the new multiplane camera which gave a realistic depth of field. The film was also credited for its ability to add new emotional depth to animated characters by building on Disney's previous learnings from *The Three Little Pigs*.

Following *Snow White and the Seven Dwarfs*, the Disney studios released a wave of outstanding feature-length animation films that have gone on to become classics, including *Pinocchio* (1940), *Fantasia* (1940), *Dumbo* (1941), and *Bambi* (1942).

Perhaps the most brave and impossible of these films to realize was *Fantasia*. Science fiction writer Ray Bradbury recalls of seeing *Fantasia* as a child and notes that it was one of the seminal childhood experiences to trigger his creative imagination (Greasley in Wise 2014, p. 152). *Fantasia* is a case in point of Walt Disney's do or die efforts in making his dreams come to reality. *Fantasia* cost almost \$2.3 million but it had limited box office success because its show engagements were limited by the unavailability of enough Fantasound equipment to screen the new sound techniques used properly and the fact that revenues from Europe were affected by World War II. Disney himself was unsatisfied with how his

vision translated into reality in the film. He said: "I wanted a special show just like Cinerama plays today [in 1956] . . . I had *Fantasia* set for a wide screen. I had dimensional sound . . . To get that wide screen I had the projector running sideways . . . I had the double frame. But I didn't get to building my cameras or my projectors because the money problem came in . . . The compromise was that it finally went out standard [that is, standard screen dimensions] with dimensional sound. I think if I'd had the money and I could have gone ahead I'd have had a really sensational show at that time" (Disney in Barrier 2007, p. 162).

Making the Impossible Possible: The Power of Imagination and Determination

It would seem that the quest to realize his many ideas was what drove Disney with varying degrees of impact upon and success in his professional and personal relationships. His singlemindedness and determination to elevate animation from short form to long form is demonstrated in the following speech to his employees in 1941.

In the twenty years I have spent in this business, I have weathered many storms. It has been far from easy sailing. It has required a great deal of hard work, struggle, determination, confidence, faith, and above all, unselfishness. Perhaps the greatest single factor has been our unselfish attitude toward our work. I have had a stubborn, blind confidence in the cartoon medium, a determination to show the sceptics that the animated cartoon was deserving of a better place; that it was more than a mere 'filler' on a program; that it was more than a novelty; that it could be one of the greatest mediums of fantasy and entertainment yet developed. That faith, confidence and determination and unselfish attitude has brought the cartoon to the place that it now occupies in the entertainment world. (Barrier 2007, p. 4).

In this speech Disney then goes on to underline his belief in the power of his own imagination and determination.

To me, the future of the business has never looked better. The possibilities in this organization have never looked better. And I can assure you boys that I still have plenty of pep and fight left in me,

and I have the utmost confidence in my ability to solve our problems and to run this business; and I want you to know that I am raring to go. Here is the answer to the crisis with which we're confronted. I'll put it in a nutshell. There are three things: quality production is number one; efficient operation is number two, which leads to the third—production turnover. That is the solution to this whole thing. Simplifying it down to the individual, I would say that . . . the whole thing, is this: A good honest day's work. Believe me, that will be a cure for all our problems. You can't deny that it is individual efficiency that leads to collective efficiency . . . This business has been, and still is, a pioneering venture. Every one of you men here today are pioneers. Most of you are young, and a big percentage of you— a very large percentage of you— have been in this business less than five years. Regardless of what you think, you've got a hell of a lot to learn. Regardless of what you think about conditions, every one of you should feel lucky that you're in the business that you intend to make your career. We should all feel fortunate that we are here, that we have a chance, that we're in on the ground floor. Probably throughout the country there are many men who are more capable than any one of us who don't even have the chance to secure an art education, or even maybe a high school education. I honestly believe that instead of complaining, we should count our blessings. This business is ready to go ahead. If you want to go ahead with it, you've got to be prepared— you've got to be ready for some hard work— you've got to strengthen yourselves in every way— you've got to make yourselves strong. If the business is to survive the many storms that are ahead of it, it must be made strong; and that strength comes from the individual strength of the employees. (Barrier 2007, p. 162)

Barrier reports that this speech alienated employees as Disney was at the time attempting to turn them away from joining the Screen Cartoonists Guild.

Towards the Creation of a Fantastical World

Walt Disney once explained how he directed imagination to wide range of ideas: "To some people, I am a kind of Merlin who takes a lot of crazy chances but rarely makes mistakes. I've made some bad ones. But fortunately, the successes have come along fast enough to cover up the mistakes. When you go into bat as many times

as I do, you're bound to get a good average" (Disney quoted in Lynch 2001, np).

In the two decades preceding his death, Disney was engaged in a number of creative enterprises which stand testament to the diversity of his vision of the possible. During World War II he serviced and supported the American Government's war effort. In the 1950s he became fascinated with the then new technology of television. In 1954 he started Disneyland, an hour long anthology television show of animated cartoons, live action features, and other materials from his studio archives. During this period the Mickey Mouse Club (1955–1959) emerged as a highly successful variety show aimed at children. In the early 1960s Disney continued to create work across a number of fronts including the highly successful feature length fantasy film *Mary Poppins* (1964) which combined animation and live action.

In the last decade of his life Disney worked towards establishing what has become a living legacy to his vision of the fantastical world. In 1952 he wrote to his sister, Ruth, about his idea for a miniature touring show of Americana, which at one point was to be called "Disneylandia." He said:

I've been collecting all sorts of miniature pieces for the past three or four years, with this project in mind. It's been a wonderful hobby for me and I find it is something very relaxing to turn to when studio problems become too hectic" (Barrier 2007, p. 233). In his biography of Disney, Barrier notes that March 27, 1952, the Burbank Daily Review quoted Disney as saying that "Disneyland will be something of a fair, an exhibition, a playground, a community centre, a museum of living facts and a showplace of beauty and magic" (Barrier 2007, p. 233). Barrier also notes the existence of a 1953 "pitch kit," which described the impossible dream of "Disneyland's "lands" in considerable detail, and the park itself in fulsome language: The idea of Disneyland is a simple one. It will be a place for people to find happiness and knowledge. It will be a place for parents and children to share pleasant times in one another's company, a place for teacher and pupils to discover greater ways of understanding and education. Here the older generation can recapture the nostalgia of days gone by, and the younger generation can savour the challenge of the future. Here will be the wonders of Nature and Man for all to see and understand. (Barrier 2007, p. 243)

Conclusion

Disneyland is the ultimate fantasy land and living monument to Disney's ability to turn what some would say is an impossible dream into reality and thus enrich the lives of others. However, Disney also believed in the power of education to assist others to transform their dreams into reality. Disney was instrumental in establishing California Institute for the Arts, or CalArts. Disney's (who was chairman of the board of trustees) preface to the fundraising brochure for the institute, "To enrich the lives of all people" proposes:

The remarkable thing that's taking place in almost every field of endeavour is an accelerating rate of dynamic growth and change. The arts, which have historically symbolized the advance of human progress, must match this growth if they are going to maintain their value in, and influence on, society. The talents of musicians, the self-expression of the actor, and the techniques and applications of fine and commercial artists are being used more and more in today's business, industry, entertainment and communications—not by themselves, but rather, in close association with each other. So artists who can operate in only one field are finding themselves limited and ill-equipped to meet the challenges and opportunities that come their way. What we must have, then, is a completely new approach to training in the arts—an entirely new educational concept which will properly prepare artists and give them the vital tools so necessary for working in, and drawing from, every field of creativity and performance. (Barrier 2007, 299)

Perhaps the most important legacy to the memory of Walt Disney the man who valued the place of the impossible in life, is a sign at the entrance to Disneyland which reads: "Here you leave today behind and enter the world of yesterday, tomorrow and fantasy" (Huebner 2009, p. 228).

The Possible in the Life and Work of William Grey Walter

Louise Barrett

University of Lethbridge, Lethbridge, AB, Canada

Abstract

William Grey Walter was a pioneer of both electroencephalography (EEG) and cybernetics (the science of control systems). Trained as a neurophysiologist, he was possessed of the technical skill and the imagination to develop EEG into both a diagnostic tool and a means of offering insight into the function of the living brain. His work in cybernetics was far ahead of its time, and he can rightly be considered the father of biologically inspired robotics. His robotic "tortoises" were physical models of the brain based on principles drawn from his EEG work and also represent the first example of behavior-based robotics. Walter was a visionary who recognized the possibility of EEG for studying the living brain and saw how simple physical models could provide deep theoretical insights. Walter's work has only recently been rediscovered and recognized for its originality, creativity, and exuberant delight in exploring the bounds of the possible.

Keywords

Grey Walter · Cybernetics · EEG · Behavior-based robotics · Alpha wave · Neurophysiology

Introduction

If anyone deserves an entry into an encyclopedia of the possible, it is the neurophysiologist and

cybernetician, William Grey Walter (1910–1977). His work explored the bounds of the possible with respect to both the questions he asked and the means used to pursue the answers. A pioneer in the field of electroencephalography (EEG, a technique to measure the electrical activity of the brain via electrodes placed on the scalp), he conducted revolutionary work into the detection of brain tumors via the presence of delta waves, as well as work linking individual differences to variation in alpha, delta, and theta waves. He was also interested in the kinds of altered states of consciousness that could be induced by stroboscopic light (“flicker”) and performed some of the first work in “biofeedback” (the use of visual feedback to control one’s own brain waves) (see Walter 1953; Pickering 2010 for review). Walter is, however, best known for his work in cybernetics (the science of control systems), where he developed the first biologically inspired robots and initiated the field of behavior-based robotics (Walter 1950, 1951, 1953). In this domain, possibility infused his entire enterprise – the adaptive cybernetic systems that interested Walter were imbued with the sense that genuine forms of novelty could, and would, emerge, even when each component of the system was well understood individually: knowledge of a system could only be known through its performance and could not be specified in advance.

The broader discipline of cybernetics itself also spoke to possibility. Unlike American cybernetics, which emerged from military research, the British cyberneticians, of whom Grey Walter was a leading light, were (literally) a less disciplined bunch: more interested in biology and brains than military weapons, they came from a variety of backgrounds; favored dining clubs and informal, relaxed meetings (the Ratio club being the most famous instantiation of this); and mostly pursued cybernetics as enthusiastic amateurs and hobbyists, holding down positions in other fields (Boden 2008; Pickering 2010). A lack of university departments and dedicated research institutions meant that British cybernetics was always a rather marginal subject: cyberneticians had no way to “reproduce themselves,” via their PhD students, nor to direct and sustain the field through time. It was, as Pickering (2010, p. 11) calls it, a “nomad science,

perpetually wandering and never finding a stable home.” While this did not bode well for the future of the field – cybernetics faded quickly with the rise of cognitive, computational AI – this lack of “disciplinary policing” (Pickering 2010, p. 60) enabled postwar cybernetics to escape its narrow academic bounds, infiltrating fields as diverse as architecture, poetry, literature, television, and music. Grey Walter’s work, in particular, gained popular attention, and Aldous Huxley, William Burroughs, and John Cage were all variously inspired and influenced by his book, *The Living Brain* (Pickering 2010).

Biographical Details: Birth to Bristol

Grey Walter – as he was always known, he never went by William – was born in 1910, in Kansas City, USA, to a British father and an American mother, both of whom were journalists. His parents moved to England just after the First World War in 1915, and Walter remained there for the rest of his life. He attended Westminster School and then went on to Cambridge, where he obtained a first in neurophysiology at King’s College (Hayward 2001; Holland 2003). He continued with postgraduate work for a further 4 years, producing a dissertation on “Conduction in nerve and muscle.” His hope was that this would result in a Fellowship at Cambridge, but this was not to be. His son, Nicholas Walter, noted that this was a source of deep disappointment to his father (Holland 2003), but perhaps this was ultimately to Walter Senior’s benefit. Neurophysiology at Oxbridge between the wars was a circumspect, conservative endeavor that “ended at the top of the spinal cord” as Walter (1953, p. 27) himself put it. At Cambridge, E. D. Adrian’s group was investigating the electrical potential and mechanisms of conduction in individual nerve fibers, while at Oxford, Charles Scott Sherrington’s group was engaged in the reconstruction of the reflex pathways of the spinal cord. The direct investigation of the brain itself – the subject that most interested Walter – was seemingly taboo: it was one thing to measure the properties of nerve cells and study reflex actions where carefully

controlled experimental methods could be brought to bear, but “Cambridge still could not accept the brain as a proper study for the physiologist” (Walter 1953, p. 53). Such conservatism did not sit well with Walter, who favored a more free-wheeling, anarchic approach:

Any man or woman who is a scientist by avocation as well as by education is a natural anarchist: the laws of science are no man-made law; they are the parameters of man’s hypothetical vision of the orderly processes of life and expendable in the first moment of inadequacy or redundancy. (Walter 1956, p. 68)

Walter’s failure to secure a Cambridge Fellowship enabled him to take up an invitation by the psychiatrist, Frederic Golla, to join his research team at the Central Pathological Laboratory at the Maudsley Hospital in London (Bladin 2006; Hayward 2001). Golla’s philosophy was much more in line with Walter’s own, recognizing the environmental and physiological origins of conscious states and showing a greater willingness to conduct research that could link the world of science to the world of human values. Walter joined Golla at the Maudsley in 1934, and then, in 1939, they both left to take up positions at the Burden Neurological Institute, which had just opened outside Bristol; Walter remained here for the rest of his working life.

Walter’s move to Golla’s group allowed him the freedom to explore the possibilities of EEG to the full. At Cambridge, the German psychiatrist, Hans Berger’s 1928 discovery of electrical waves in the brain had been met with skepticism: Berger’s “. . .wobbly line did not convince us or anybody else at that time... His entirely original and painstaking work received little recognition” (Walter 1953, p. 53). It was only in 1934, when Adrian and his colleague Brian Matthews themselves demonstrated the “Berger rhythm” (later called the alpha rhythm), that anyone took Berger’s work seriously, although Adrian and Matthews were not entirely enthusiastic, reporting the rhythm to be “disappointingly constant” (Adrian and Matthews 1934).

Frederic Golla, however, had immediately recognized the potential of EEG, and his confidence in the method only grew with the Cambridge results.

Golla enquired of Adrian if he knew of anyone who could build and apply a clinically useful version of the EEG. Adrian recommended Walter. After a visit to Germany to consult with Berger (where Walter discovered that Berger knew nothing of electricity or mechanics), Walter set about constructing, developing, and testing his own EEG machine, a task to which he was well suited as he was “a genius at tackling this kind of problem. . .making impossible things work” (Bladin 2006, p. 172).

Walter’s enthusiasm and energy meant that the establishment of EEG as a useful and clinically relevant technology did not have to wait long: in 1936, he discovered delta rhythms, large slow waves that were indicative of both the presence of cerebral brain tumors and epilepsy. EEG thus moved from being viewed simply as the “wobbly line” of a German psychiatrist to a source of diagnostic authority (Hayward 2001). From this point on, EEG became widely accepted within psychiatry, forming a routine part of hospital examinations. Due to Walter’s efforts, it also moved beyond the bounds of the hospital to more commercial uses, including personality assessments and the establishment of criminal responsibility (Hayward 2001).

Once established at the Burden Neurological Institute (BNI), Walter was even more determined to show how EEG could be connected to human behavior. Building on a suggestion by the Cambridge psychologist, Kenneth Craik, Walter conceptualized alpha waves as a form of scanning mechanism in the visual cortex – a hunt for visual input (Walter 1953). Such a model could explain why the alpha waves were “disappointingly constant” and also why they disappeared when people opened their eyes or thought about an object. From this, Walter reasoned that different forms of alpha waves could indicate different forms of imagination: those with highly persistent alpha waves would have little in the way of visual imagination, whereas those in whom the alpha waves were reduced were obviously enjoying a rich inner life (Walter 1953).

Walter also reconceptualized other patterns of brain activity. Further work on delta rhythms revealed them to present in almost all children

below the age of 9, in addition to being indicators of brain cancer. The persistence of delta waves beyond the age of 9 was, however, interpreted as a sign of pathology and argued to represent an increased risk of juvenile delinquency. Walter (1953), in contrast, noted that such waves persisted in those children who were most easily led; his interpretation, therefore, was that the waves were indicating a search for stability, rather than a risk of degenerate behavior. Theta waves, meanwhile, which had been observed in children as well as those designated as psychopaths, were interpreted initially as indicators of anger and aggression. Walter argued instead that these should be seen as indicators of frustration and loss after the removal of a pleasurable stimulus: his team had first seen theta rhythms in a French student undergoing a routine EEG test, who produced bursts of theta waves every time an accompanying nurse, who was stroking his head during the test, removed her hand. Theta waves, Walter suggested, represented the search for a pleasurable entity (Walter 1953).

Walter also helped EEG “escape from the laboratory” and capture the public imagination. A key element in this was Walter’s natural flair for showmanship; as Hayward (2001, p. 616) puts it: “At a time when the incipient field of neurophysiology was dominated by the reserved and stately figures of Edgar Douglas Adrian and Charles Scott Sherrington, Walter cultivated a more swashbuckling image as an emotional adventurer.” Thus, when Walter and his BNI colleagues discovered that couples and friends tended to share similar alpha-wave patterns, Walter was quick to speculate that marital harmony could depend on alpha-wave compatibility and “made great play of the EEG’s new-found romantic utility, arguing in interviews with *Life Magazine* and on the BBC radio program, *The Brain’s Trust*, that young couples should be routinely tested” (Hayward 2001, p. 626). It should also be mentioned that when Walter swapped wives with his local greengrocer – an emotional adventurer indeed – he discovered that his new spouse had alpha rhythms very different from his own, which led him to reconfigure his theory entirely. Now, contrasting rhythms formed the basis of a “mutually regulating combination,” with love as a

positive transformative influence (Walter 1961, p. 16). By the late 1960s, Walter was arguing that EEG knowledge could even be crucial to world peace: “It may even be that serious crises between nations . . . have arisen because the negotiators have different kinds of imagery and can only talk at cross purposes” (Walter 1968, p. 184).

While Walter’s interpretations and recommendations may have been overblown, it would be fair to say that they were never conclusively wrong. More importantly, Walter’s willingness to tie EEG to real-life concerns, like the human need for love and belonging, offered up a new vision for neuropsychology, at a time when such topics were considered off-limits by most other scientists. Walter’s work on brain tumors and delta waves was also truly revolutionary – long before the likes of fMRI and PET scans, EEG was the only noninvasive means of assessing the health of the living brain. Indeed, Walter’s work on tumors was recognized in the 1945 *Atlas of Electroencephalography* as “the significant pioneering work in this area” (Bladin 2006, p. 172). Walter also developed other machines, in addition to the EEG, to assist with the interpretation of EEG recordings, including both a frequency analyzer (that could pull apart a complex tracing into its component frequencies) and a “toposcope” that presented a visual snapshot of electrical activity projected onto a model of the head (Walter 1953; Bladin 2006). Walter also contributed to his field by founding the EEG society, organizing the first EEG congress, and cofounding the EEG journal. As Harold Shipton (1977, p.iii) wrote in his obituary for Walter: “Few scientific disciplines owe as much to one man as electroencephalography and clinical neurophysiology owe to Grey.”

Our Little Robots in Bristol

Walter’s work in cybernetics – including his famous robot tortoises, Elsie and Elmer – can seem like an unrelated offshoot of his EEG work; an impression reinforced by media coverage at the time, with BBC newsreels declaring “In a modest villa on the outskirts of Bristol lives Dr Grey

Walter, a neurologist, who makes robots as a hobby,” and newspaper reports suggesting that “Toys which feed themselves, sleep, think, walk, and do tricks like a domestic animal may go into Tommy’s Christmas stocking in 1950, said brain specialist Dr. Grey Walter in Bristol last night.” Viewing his cybernetic efforts this way would be a mistake, however: despite Walter’s own descriptions of them as toys, Walter’s robots were intellectual tools, representing physical models of the brain.

In his book *The Living Brain*, Walter accounts for the origins of his tortoises via a discussion of the difficulties inherent in building a scale model of a human brain. After describing the trials of designing and constructing a single model nerve cell, he goes on to point out that, even if it were possible to manufacture a sufficient number to produce a reasonable sized artificial brain, millions of cubic feet of warehousing would be also be needed for storage. And, of course, this doesn’t even begin to touch on the financial costs, which would be equally monstrous: although a single nerve fiber might be made “for about a dime,” it would cost \$1,000,000,000 to manufacture a whole brain’s worth, plus there would be the costs of connecting them all, which Walter calculated would run to about \$2,000,000,000,000,000,000. Once this stage was reached, it would then require around a million kilowatts of power to run this artificial brain. Given these “incalculable costs”, Walter suggested a different approach was needed. Rather than assuming that the performance of the living brain was a sole function of the number of neurons, one could ask instead whether the “elaboration of cerebral functions may possibly derive. . .from the richness of their interconnections” (Walter 1953).

Elmer and Elsie, the robot tortoises (their nicknames were based on the initials of the terms Walter used to describe them – electromechanical robots, light sensitive with internal and external stability), were therefore built as a way to test this idea. Each tortoise – or *Machina speculatrix* to give them their Latin name – was built with, in effect, only two neurons: “two miniature radio tubes, two sense organs, one for light and one for touch, and two effectors or motors, one for crawling and the other for steering” (Walter 1950, p. 43), with power

supplied by a hearing aid battery (for the tubes) and a miniature 6-volt battery (for the motors). In appearance, the robots looked like small motorized tricycles when “naked,” but when fitted with their “shells,” they indeed looked very much like tortoises. The shell was not just for effect, however, but an integral part of the touch reflex and acted as a pressure sensor. The shell was mounted on a rubber touch contact, so that it dangled freely. When the tortoise moved on the level, with the shell not touching anything, the contact was an open circuit. If the tortoise bumped into an obstacle, however, displacing the shell from its usual position, the contact closed, and the touch reflex was activated. The light reflex of *M. speculatrix* was more directly related to Walter’s EEG work. The light sensor was a photoelectric cell mounted on the front of the steering column. The cell was covered with a “hood” that blocked out light from all directions except the front and was fitted with a “running light” (a small headlamp) that indicated whether the steering motor was switched on, so that Walter could tell it was working correctly. The steering column was designed to rotate around its own axis so that, when switched on, the photoelectric cell would “scan” the environment in search of a light source – in much the same way that Walter had suggested alpha waves scanned in search of input. As such, *M. speculatrix* could be seen as both simple model of the living brain and a model of a simple living organism.

With their sense organs in place, the robots were wired up so that they would seek out light sources and attempt to overcome obstacles. In the absence of an immediately detectable light source, the driving motor attached to the front wheel would operate at half-speed propelling the robot forward, while the motor on steering column would rotate the front wheel at full speed (the back wheels were not powered but ran free). The circular motion of the steering column combined with the forward motion provided by the driving motor meant that the tortoise moved in a series of slow, exploratory loops around its environment.

If, during one of these loops, the photocell on the steering column was activated by a light source, the steering motor would stop, the rotation of steering column would cease, and the headlamp

would turn off. At the same time, the driving motor would be switched to full speed. From a behavioral perspective, the detection of a light source would thus lead the tortoise to stop its slow exploratory scanning and instead make a beeline for the light – that is, it would show a positive phototropism. If the tortoise approached a light source too closely, however, its behavior pattern would again shift, this time to “dazzle” mode, designed to enable it to avoid overly bright light. In this case, the steering motor switched on, but only at half-speed, while the driving motor would keep going at full speed so that, instead of reverting to its slow scanning behavior, the “dazzled” tortoise would veer away from the light smoothly before it bumped into it. Walter (1953) referred to this as a negative phototropism, but as Holland (2003) points out, this is not quite right: the dazzle mode is not the opposite of the positive phototropism, but rather simply the exploratory mode being run at different motor speeds. The negative feedback loop of the light reflex was thus designed to enable the tortoises to seek an “optimum” amount of light – neither too bright nor too dim.

Rather than the negative feedback loop used in the light reflex, the touch reflex was based on positive feedback. When the contact on the shell was closed by the tortoise coming into contact with an object, the signal from the light sensor was “ignored” – that is, the vacuum tubes that usually acted as amplifiers of the light signal instead formed part of an oscillating signal: both the driving and steering motors ran at full power, switched off, and then switched on again. Behaviorally, this meant the tortoise would repeatedly bash itself against the obstacle, until it had either pushed it out of the way or managed to move past it.

What made the tortoises particularly interesting to Walter was the way they not only displayed an impressive ability to cope with an uncertain environment via their behavioral tropisms, but how they displayed emergent behaviors that had not been wired into them. So, for example, the tortoises proved adept at “tidying up” their environment: their touch reflex would lead them to push obstacles out of the way in order to get past

them, with the result that, after a time, all the obstacles would be lined up neatly against the walls. This also made the environment much easier for the tortoises to navigate; thus, they not only adapted to their environment, but there was also a sense in which, as a result of their actions, the environment became adapted to them as another form of feedback loop. Another emergent behavior occurred when Walter displayed his tortoises at a meeting of the British Association for the Advancement of Science and discovered that they seemed to have an inherent preference for women over men: the light reflecting from women’s nylon stocking apparently was sufficient to attract the tortoises’ attention, unlike men’s trouser legs.

The tortoises’ reflexes could also work in concert to produce some remarkably flexible and lifelike behavior. For example, although the headlamp had been installed merely to indicate that the tortoises were running properly to their human observers, it also led to some interesting social behavior. If both tortoises were allowed to wander around the same area, they would sometimes detect and be attracted to each other’s headlamps. The detection of light would switch the tortoises into their “beeline” mode, but of course, this required the steering motor to be switched off and hence their headlamps be turned off. The disappearance of the light stimulus would switch the tortoises back to their scanning mode, which meant the headlamps would come on again. The tortoises would thus detect the other’s presence and head toward each other, but this very act would lead to the disappearance of the light to which they had been attracted. The upshot of all this was a performance that looked like some kind of “mating dance,” one in which “the machines cannot escape from one another; but nor can they ever communicate their ‘desire’” (Walter 1953, p. 129). Something similar happened when a lone tortoise was confronted with a mirror. Here, the tortoise would be attracted by the reflection of its own headlamp and switch modes to approach it directly. As in the case above, detection of the light would immediately extinguish the headlamp, resulting in a switch back to the exploratory scanning mode. Of course, the headlamp would then

come on again and be reflected in the mirror which would attract the tortoise, which would switch modes, which would switch off the light, which would switch the tortoise back to exploratory mode, and so on. The feedback circuit set up between the tortoise and the mirror gave every impression that the tortoise was somehow performing in front of the mirror and attempting to inspect its reflection, “lingering, twittering and jiggling like a clumsy Narcissus” (Walter 1953, p. 128). Walter further suggested that “on a purely empirical basis, if it were observed in an animal, might be accepted as evidence of some degree of self-awareness” (Walter 1953, p. 128).

One thing the tortoises were not able to do, however, was learn from their experience. Walter therefore cannibalized Elsie to develop a more advanced mechanical creature that could learn via classical conditioning. This one was named CORA, which stood for COnditioned Reflex Analogue; Walter also gave CORA the Latin name, *Machina docilis* – the “teachable” or “easily taught” machine. Again, Walter was ahead of his time: the design of CORA echoes the “subsumption architecture” invented and used to great effect by MIT roboticist, Rodney Brooks (inventor of the autonomous vacuum cleaner, the Roomba), where different layers of a robot’s control system work in sequence. In Walter’s design, repeated inputs simultaneously occurring in two different sensory channels could be detected by CORA, and once a given threshold of repetition was reached, a link would open between one sense and the other, enabling input to one sensory channel to predict likely input to the other. More concretely, if a whistle was blown every time light was detected, CORA would eventually learn to respond to the whistle as though it was the light. Similarly, if the whistle was associated with colliding with an obstacle and withdrawing, CORA could learn to withdraw based on the sound of the whistle alone. In this way, Walter discovered that he could induce “neuroses” in his creature: if the machine was conditioned so that it would approach light and withdraw from an obstacle, then, on the subsequent sound of a whistle, the robot engaged in a “paradoxical withdrawal,” whereby the “natural” attraction to the light was

extinguished, “and the model can no longer approach its source of nourishment” (Walter 1951, p. 62).

Like the tortoises, it is clear that Walter’s EEG work inspired certain aspects of CORA’s design: “memories” were formed by electrical oscillations in a feedback circuit, and the model “forgot” as those oscillations decayed over time. In addition, when several learning pathways were present, the complex of memories formed could be represented by synthesizing all the oscillations specific to each, which then generated a characteristic wave pattern, much like that seen on an EEG. Walter pointed out that “the implications of these effects are of considerable interest to those who study the brain, for the rhythmic oscillation is the prime feature of brain activity.” Aside from being ahead of his time with respect to his ideas concerning learning and statistical prediction, Pickering (2010, p. 66) also points out that Walter’s CORA was a “virtuoso piece of electrical engineering, in both its design and construction,” which “remains an unexploited resource in the history of cybernetics”: no one has ever attempted to replicate it or take the design further – Walter himself did no more robotics research after CORA. The behavior-based roboticists of the 1980s used neural networks to enable their machines to learn, not Walter-style electronics. Consequently, the focus on oscillations and rhythmic waves that so intrigued Walter, and made his machines so lifelike, has completely faded from view.

Summary: Walter’s Legacy and Impact

Grey Walter’s entire career was focused on pushing the bounds of the possible. He realized the potential of using EEG not only as a diagnostic tool but also as a means of exploring the function of the healthy, living brain in a meaningful way. His theoretical insights on neural connectivity and behavioral flexibility gave rise to the first behavior-based robots, which captured the public, as well as the scientific, imagination. His inventiveness, curiosity, and exuberance were appreciated by all who came into contact with him, inspiring

and creating new spaces of possibility for others to occupy; as it says in his obituary “there is no fitter monument to Grey than the continued tradition of limitless enquiry which survives him at Bristol” (Shipton 1977, p. iv). As so often happens, however, some of his ideas were seemingly just too far ahead of their time, and his achievements have only been fully recognized in retrospect. As Owen Holland (2003) notes, it is somewhat embarrassing that Walter’s work had so little direct influence on the development of modern behavior-based robotics: many of the field’s key achievements had to be painstakingly rediscovered and reinvented by the robotics community. Hindsight, of course, is always 20:20, and it sometimes requires a certain amount of temporal distance to appreciate when and why certain possibilities were not seized on and exploited. Holland (2003) suggests that the tortoise technology may have been too inaccessible to those without a good knowledge of postwar electronics or that his papers and books were too old-fashioned in their tone and style – a deep irony considering their futuristic possibilities. Alternatively, as Pickering (2010) suggests, the fizzling out of Walter-style robotics may have more to do with the lack of an institutional base and support for cybernetics, rather than any inherent flaws in Walter’s approach. One wonders, as Holland (2003, pp. 2117–2118) does, whether “biologically inspired robotics might have advanced further and faster if his work had not been allowed to fade away quite so fast.” Nevertheless, we can see Walter’s influence and legacy in his ability to inspire those who led the behavior-based revolution in robotics during the 1980s. Rodney Brooks (2002), for example, has written of how he attempted to build his own version of *M. speculatrix*, after reading *The Living Brain* as a child in his native Australia.

Whatever the reasons for Walter fading from view in the latter half of the twentieth century, his rediscovery toward the beginning of the twenty-first century means that, as Holland (2003, p. 2119) writes, “his work constitutes a real legacy in the traditional sense: something built up by a previous generation and preserved and passed on so that it can benefit a new generation.” Quite so. Perhaps the best way to conclude this piece, then,

is to give the last word to the man himself (or at least his father, who was the ghostwriter of his books) and his reflections on his adventures in artificial life:

As toys, they refresh the spirit of the laboratory children we all are, leading us to familiarity with more and more elaborate mechanisms. As tools they are trustworthy instruments of exploration and frequent unexpected enlightenment. As totems, they foster reverence for the life they have so laboriously been made to mime in such very humble fashion – and still would foster it even should they, creatures of “sorcery” peering into the dim “electro-biological” future in search of a *deus ex machina*, look up at us and declare that God is a physiologist. (Walter 1953, p. 132)

The Possible in the Life and Works of Sigmund Freud

Maximiliano Azcona
Universidad Nacional de La Plata, La Plata,
Argentina

Abstract

Indubitably, Sigmund Freud was one of last century's thinkers who contributed the most to redefining the scope of what *is possible* in the domain of human phenomena. He soundly charged at the picture that the western culture had formed of the human being, installing a field of inquiry and action whose potency stays current to this day. It is not an overstatement to say that psychoanalysis represented one of the most important epistemic torsions in the history of humankind, one whose implications have yet to be fully assimilated.

The objective of this brief entry, concisely addressing a few key conceptual and methodological notions, is to show how the *possible-impossible* axis built a bridge that enabled the Freudian foray into mind and culture, disrupting thus modern representations of what we have been, are and can become, as human beings.

Keywords

Psychoanalysis · Possible · Sigmund Freud · Unconscious

Unconscious

The division of the psyche into what is conscious and what is unconscious is the fundamental premise of psychoanalysis (Freud, 1923a/2004, p. 15).

Eurocentric modernity raised a body/mind dualism that led to considering consciousness as the place of reason, opposed to the universe of

unreason or madness. For a very long time, consciousness was thought as where the motivations that determine individual actions reside, as well as the inescapable resource for knowing one's own mind and the minds of our fellow human beings.

Even though Freud was not the first who used the term “unconscious” to refer to what escapes consciousness, he managed to define it conceptually with an unprecedented level, and set it as a fundamental reference for one of the most consequential theoretical systems of the twentieth century. By defining it very differently than how his forerunners did, the *unconscious* became an instance inaccessible to consciousness, but which manifests itself in a series of phenomena such as *dreams*, *lapses*, *jokes*, *symptoms*, and *cultural* expressions.

Despite the nonlinearity of Freudian conceptual evolution – so that no historical periodization fits perfectly –, three successive moments can be recognized in the case of *Unbewusste*: between 1893 and 1900, with the “dynamic unconscious” postulate; between 1900 and 1923, with the growing complexity of what could be called the “unconscious system”; and from 1923 onwards, with the “second topic” structural model. Notwithstanding these successive modifications, the term always referred to a decentered conception of subjectivity and affective processes, which continues to be the most radical premise in the contemporary psychoanalytic movement. It is not possible, nor will it be, – Freud argued – to explain mental phenomena without the concept of unconscious processes (Freud, 1915a/2004). This impossibility, far from fully disproved, is becoming more and more evident.

Psychoanalysis, as a theory and praxis, was made possible by Freud's original discovery of the dynamic role that the *defense* plays in the etiology of hysteria: “thus we obtain our concept of the unconscious from the theory of repression. The repressed is the prototype of the unconscious for us” (Freud, 1923a/2004, p. 17). It is an operation mode that involves repressing pathogenic memories along with a constant energy loss, which partially fails and results in the repressed representations returning through symptom formation. Such a mechanistic model became, due

to its explanatory power, a basic component of the Freudian program's core.

Freud came to understand that all psychic processes *are unconscious themselves* and that only some of them, without gaining access to consciousness, nevertheless become consciously apprehensible (so they can be called preconscious), and that among these, only a few become an object of consciousness, although always in a transitory manner (Freud, 1915a/2004). This is why he declared that "the unconscious is the true reality of the psyche; in its innermost nature it is as much unknown to us as the reality of the external world, and it is as incompletely presented by the data of consciousness as is the external world by the communication of our sense organs" (Freud, 1900/2004, p. 600). Namely, the unconscious can only be known through its effects, and its workings can only be known after it has "undergone transposition or translation into something conscious" (Freud, 1915a/2004, p. 161). Initially, Freud thought that that was the best definition of his new therapeutic: "Psychoanalytic work shows us every day that translation of this kind is possible. For this to come about, the analysand must overcome certain resistances – the same resistances as those which, earlier, made the material concerned into something repressed by rejecting it from the conscious" (Ibid.).

Along with the development of his second topic, Freud did not abandon the first one but conceived the psychic organization in a different way. These topical models partially overlap, without there being a univocal correspondence between the instances presented after 1920 and the three systems defined during the first topic – there are areas of the ego and superego as unconscious as the id. These developments made the "unconscious" come to have a rather qualifying connotation, an adjective for certain psychic processes.

Drive

In a way, our drive doctrine is our mythology. Drives are mythical beings, grand in their indetermination. In our work we cannot forego them for an instant, and yet we are never sure that we see them clearly (Freud, 1933a/2004, p. 88).

Freud used the term *Trieb* to designate "the work demand made upon the psychic apparatus" (Freud, 1915b/2004, p. 117) that characterizes all mental processes that tend toward an end. Unlike instincts, which are intermittent behaviors predetermined by biological inheritance, the drive is defined by its partiality, its constant push, and its lack of fixed direction. Every drive has its source in a body excitation (state of tension) and its purpose is to suppress this state of tension by means of a contingent object. In his work *Three Essays*, he inquired whether the drive is a somatic force or a psychic energy: he found it to be a borderline concept, articulating between the organic and the psychic, and he resorted to the metaphor of the "representative" to explain this nature (Freud, 1905a/2004).

Our Viennese began explicitly using the term *Trieb* in 1905 to characterize human sexuality and its unconscious aspects. Based on the study of perversions and infantile sexuality, he was able to disprove the popular opinion that confuses sexuality with genitality and that attributes a predetermined object and purpose to the sexual drive. The decomposition of the drive into its pregenital elements and its integration within an evolutionary panorama of sexuality helped establish a conceptual pillar for all his subsequent developments.

Despite its successive modifications, Freudian drive theory was always sustained within a dualism characterized by conflict. The initial model included *sexual drives* and *self-preservation drives*, whose dispute lies in the incompatibility of the ego's tendency toward body and identity unity, on the one hand, with the partial and autoerotic libidinal aspirations on the other hand. Later on, by introducing his conjectures about *narcissism*, he argued for the existence of a duo of ego-libido and object-libido, defining the conflict as how both tendencies differ and distribute the amount invested in one to the detriment of the other. Lastly, with the so-called "Turning Point of 1920," he proposed a final classification that differentiated *life drives* and *death drives*, based on the relocation of the "pleasure principle" as a secondary function with respect to a more primordial psychic regulation modality. He speculated that libido – ego and object drives – responds to a

tendency of the living towards unity and synthesis, while the from then on defined as *death drive* refers to the vast forms of human self-destruction that represent the tendency of the psyche of returning to a previous state of inorganic existence, which will end up designating, more than just a type of drive, the principle of every drive. Regardless of the philosophical conception underlying this dualism and the speculative demands that generated it, the explanatory power of *Beyond the Pleasure Principle* helped Freud to address a series of until then paradoxical clinical phenomena, such as repetition compulsion, traumatic dreams, children's play (Fort-Da), masochism and negative transference (Freud, 1920/2004). Additionally, it also helped him to later delve into a rewarding theorization on certain socio-anthropological aspects such as human aggression (Freud, 1924/2004, 1933b/2004) or cultural discontents (Freud, 1930/2004).

Despite the various conceptual traits that *Trieb* entailed at different periods of Freud's theoretical elaboration, it is a meta-psychological term that always refers to the mystery of desire, one that cannot be reduced to any causalist or hermeneutic ontology, but that is inescapable for any claim of understanding the innermost parts of human events that are manifested in suffering. Admittedly, the *witch* invoked by Freud in his speculations about the reasons and causes of psychic phenomena was in tune with the epistemological horizon of the natural sciences of his time. However, more than a century later, we do not seem to be in a better position to assess whether biology will ever be able to provide a more solid basis for the *Trieb* notion. On the other hand, it can indeed be said that the uses of this theorization have provided an explanatory stronghold against reductionist tendencies, be it hereditary biologism – where Freud also drew from – or psychology of consciousness, which are renewed in our days.

Transference

The transference, destined to be the greatest stumbling block for psychoanalysis, becomes its most powerful auxiliary when it is managed to collect it in each case and translate it to the patient (Freud, 1905b, p. 103).

The concept of “transference” designates the unconscious process of updating childhood's affective history, which Freud discovered and conceptualized as a central tool of psychoanalytic treatment.

Early on, Freud used the French term *transfert* in an article on hysteria for the famous Villaret's medical dictionary, referring to the displacement of the hysterical symptom in the body. In *Studies on Hysteria*, elaborating on the obstacles that can occur within the therapeutic relationship, he used the concept of “false link” to discuss the way in which the person of the analyst became involved in the patient's lived experiences (Freud & Breuer, 1895/2004). Later, he emphasized that becoming enamored with the analyst is a central component of transference, embodying both the driving force of the cure and the main resistance to its pursuit (Freud, 1914b/2004). Furthermore, he insisted that the analyst's response to the demand for love should not be conceding: “to yield to the demands of the transference, to fulfill the patient's wishes for affectionate and sensual satisfaction, is not only justly forbidden by moral considerations but is also completely ineffective as a technical method for attaining the purpose of the analysis” (Freud, 1926a/2004, p. 212). The abstinence ethical precept is substantiated by theory, since frustrating the patients within the transference orbit enables them to recall, re-update and address their conflicting drives. The analyst proceeds with the intent of waging a “perpetual struggle with his patient to keep in the psychical sphere all the impulses which the patient would like to direct into the motor sphere” (Freud, 1914b/2004, p. 155).

In his work *Remembering, Repeating and Working-Through*, Freud introduced the notion of “transference neurosis,” which designates how the patient repeats, in transference with the person of the analyst, childhood conflicts that they cannot remember. Repetition is explained as the staged return of what refuses to be remembered, and that is why it must happen even if the patient experiences it as his symptoms getting worse, since “it is not possible to take down an enemy who is absent or not close enough” (Freud, 1914a/2004, p. 154). The analyst's challenge is to sustain the transference without reciprocating it, and wait

for the symptoms to organize themselves within, intervening on the resistances and encouraging the working-through: “this working-through of the resistances (...) is a part of the work which effects the greatest changes in the patient and which distinguishes analytic treatment from any kind of treatment by suggestion” (Freud, 1914a/2004, p. 157). In this sense, the “false link” with the person of the analyst becomes an indispensable mistake for the expected course of all psychoanalytic treatment: transference is not so much an analysis tool as the very ground on which the cure takes place.

Even though Freud elaborated on its workings within the analytic relationship framework, he always admitted that transference is a strange phenomenon of intersubjective communication, one in which the conflict of impulses and fantasies of significant links from the past are reissued in the present relationships. Thanks to the notion of transference it was possible to shed light on how all kinds of human links are created and sustained, especially those based on some type of asymmetry – teacher-student, doctor-patient, leader-masses, etc. At the same time, it helped appreciate the role of the historical-social matrices, individually and collectively, to better understand not only the present, but also future relational possibilities.

Psychoanalytic Method

Basing myself on the ‘cathartic’ method introduced by Josef Breuer, I have in recent years almost completely worked out a therapeutic procedure which I propose to describe as ‘psychoanalytic’ (Freud, 1898/2004, p. 275).

Freud worked by evolving his ideas so they provide a more satisfactory answer to the procedural and theoretical problems he was working on. In his early years, he made use of the moral and medical treatments inherited by the tradition of psychiatrists and neurologists: rest, whirlpool baths, nutrition, electricity (Freud, 1887/1986, p. 38). While he used them in combination, and even continued using them as his own technical inventions advanced, he declared their

insufficiency and linked it to his movement’s inception: “Psychoanalysis was born out of medical necessity. It sprang from the need for bringing help to neurotic patients, who had found no relief through rest-cures, through the arts of hydropathy or through electrotherapy” (Freud, 1919/2004, p. 255).

The heated controversy between the French schools of *La Salpêtrière* and *Nancy* framed Freud’s foray into hypnosis in December 1887, with which he said he had attained “all kinds of small but amazing achievements” (Freud, 1887/1986, p. 5) and that at first, he combined with the aforementioned traditional techniques (Freud, 1891/2004, p. 143) for the sake of two objectives: to eliminate pathogenic memories and impose different ideas on the patient. This course of prohibitive hypnotic suggestion, as direct as unsatisfactory, was surpassed when the Viennese continued attempting to approach the “symptoms” causes and plunged into the application of the “cathartic method” created by Breuer. This meant “removing the result of the ideas that have not been abreacted, either by reviving the trauma in a state of somnambulism, and then abreacting and correcting it, or by bringing it into normal consciousness under comparatively light hypnosis” (Freud, 1893/2004, p. 186). The next step was using catharsis unmediated by hypnosis, with the purpose of treating what had already begun to be understood as the result of conflict and defense, which would end in an irreversible epistemological transition from the observation field to the listening field.

By extending the idea of physical trauma to the orbit of the psyche, he conceived “traumatic situations” associated to the patients’ sex life which caused the psychoneurosis *a posteriori*. This “seduction theory,” an intermediate link in the Freudian conceptual chain, was developed until the place of “fantasies” and “screen-memories” could be explained and, consequently, the role played by infant sexuality and the Oedipus complex in psychic reality. The realization that “it is quite hopeless to try to penetrate directly to the nucleus of the pathogenic organization” (Freud & Breuer, 1895/2004, p. 297) concluded in the development of the “free association” method,

made possible not only by the clinical experience obtained with his patients but also from his “self-analysis” experience. This new technique, “far superior to the old, and indeed there can be no doubt that it is the only possible one” (Freud, 1905b/2004, p. 11), was elaborately described in the second chapter of his magnum opus on dreams but only in 1909 would it be defined as the “main rule of psychoanalysis” (Freud, 1909/2004, p. 28). It was based on the conviction that the free will apparently involved in patients’ spontaneous occurrences was actually illusory, since it “reveals that it is strictly determined in a way that would really never have been thought possible” (Freud, 1901/2004, p. 234).

This decisive modification of his technique was accompanied by important theoretical and procedural formulations, such as the worth of “interpretation” and “construction” of unconscious representations and their conceptualization as “overdetermined” phenomena manifested “retroactively.” These last two aspects (Nachträglich and Überdeterminierung) reveal a philosophical conception of temporality and causality that was profoundly disruptive with the linearity of the scientific models of the time and that even today can be regarded as one of the axes that best display the complexity of mental phenomena mechanisms.

Despite the passing of the years, Freud invented a method at the beginning of the last century whose essence remains in force as one of the most fruitful paths for understanding and modifying countless mental conditions. This procedure made all forms of contemporary psychotherapy possible, since nowadays there does not seem to exist any recognized psychotherapeutic method, either with claims of continuation, opposition, or improvement, which is not somehow related to Freudian psychoanalysis.

Conclusion: Psychoanalysis, an Impossible Profession

Its [psychoanalysis’] original significance was purely therapeutic: it aimed at creating a new and efficient method for treating neurotic illnesses. But

connections which could not be foreseen in the beginning caused psychoanalysis to reach out far beyond its original aim. It ended by claiming to have set our whole view of mental life upon a new basis. . . (Freud, 1925/2004, p. 228).

Psychoanalysis allowed a better understanding of the similarities between the paths that lead both to neurosis and to artistic, scientific, philosophical, or religious creation, generating a complete reformulation of the health-disease binomial. Passing from the clinical to the cultural was “an irresistible temptation and, indeed, a scientific duty” (Freud, 1919/2004, p. 257) that was woven in an extraordinary warp of knowledge about human affairs. The Enlightenment affiliation of Freud’s education allowed him to make use of the scientific knowledge of his time to end up establishing a revolutionary discipline that, even today, stands *against* the most deeply rooted philosophical and anthropological assumptions of modern Western culture.

The tripartition in which Freud defined psychoanalysis – “a procedure for investigating the unconscious, a method for treating neurotic disorders and a nascent scientific discipline” (Freud, 1923b/2004, p. 231) – did not keep him from considering it, along with education and government, an “impossible profession,” insofar as “one can be sure beforehand of achieving unsatisfying results” (Freud, 1937/2004, p. 249). Admittedly, such impossibility does not make psychoanalysis – neither teaching, nor politics – unattainable, but refers to the impediment of possessing a prior know-how that guarantees the total realization of its desired results. Each encounter between human beings that occurs within the analytical device renews this essential uncertainty, preserving it from any aspiration of becoming a mechanically applicable technology. In a digitized and commoditized world in which not a few dream of psychotherapeutic recipes for a standardized and “efficient” approach to treat all psychopathologies, such impossibility is perhaps one of its greatest virtues.

Thus far, time seems to be proving Freud right in that “the future will probably attribute far greater importance to psychoanalysis as the science of the unconscious than as a therapeutic

procedure” (Freud, 1926b/2004, p. 253). Despite the typical adversaries who long for its annihilation, psychoanalysis is very much alive and in thriving disciplinary growth. Deep down, we all know that to dispense with it would not only neglect a successful approach to various psychic suffering modes, but fundamentally one of the most prolific fields and the most promising methods of elucidating the human creation processes, in their broadest possible sense.

Possible in Visual Arts

Julianna Sandholm-Bark

Webster University Geneva, Geneva, Switzerland

Abstract

This entry begins with an attempt to classify the broad term of the “visual arts” in terms of a closed versus open system. In the paragraphs that follow, I’ve made some attempt to retain

some kind of chronology, as I discuss various distinctive aspects of the visual arts. Starting with paleolithic cave painting, control of technique, and mastery over medium, the idea of art as poxy, art and nation building, art as commodity, and concluding some amazing artists out there who are pushing our idea of what art is.

Visual arts · Art · Artist · Art making · Possible

Defining the Visual Arts

At the broadest level, the term “visual arts” encompasses a wide scope of artifacts or acts – either material or immaterial – from every historical period and geographical area of human civilization. These include objects such as Greek pots, Roman sarcophagi, Flemish tapestries, Islamic calligraphy, coins and carpets, Japanese swords and vessels, Aboriginal boomerangs and dot paintings, North American quilts, Eskimo kayaks, and Yoruba ibeji, to name just a few examples. For many people, art continues to be a tangible entity, such as a painting, a sculpture, or a photograph. When placed in a museum, objects such as these play an important role as icons of a particular cultural tradition.

Since the 1960s and 1970s, the visual arts have continued to evolve in new, and sometimes less material directions. Today, the scope of visual arts production has become more diverse than ever and includes not just material artifacts but also immaterial acts (e.g., performances and participatory art) that are ephemeral and which must be documented to be seen after the fact. These intangible kinds of art resist commodification and rely on a new kind of relationship with the viewer who is expected to be an active participant in the process of art making and/or meaning making. As the visual arts of the twenty-first century have become more collaborative and participatory, they have become more difficult to define. Visual artists working today employ a great variety of mediums. While some artists continue to work in traditional mediums, others use new materials (e.g., technology) or seek inspiration from other

disciplines, such as politics or science. Some have become superstars whose work is featured at the most prestigious art fairs of the world. Others labor in conditions of quasi-anonymity, sometimes thanks to the support of mission-driven art organizations. Whatever the circumstances surrounding an artist’s artistic impulse, the existence of the innumerable artworks that populate our institutions, public spaces and homes serve as evidence that human beings have always had an inherent need to create art – art, that is to say, something that extends beyond and complements our everyday reality.

I teach a course called Current Art To Undergraduate Students and I generally like to start this course with Gombrich’s well-known quote that “There really is no such thing as Art. There are only artists” (Gombrich 1995). Students are not always aware that there are people out there who make a living as professional artists. Much of what we do in class is learn about how artists do what they do, who they interact with, and what needs to happen in order for their work to attain cultural and commercial value. Much of my course seeks to define the meaning of art according to a narrow and institutional view of the art world. This narrow view defines the artist as a particular kind of human being who desires to be an artist above all else (or sometimes the kind of human being who cannot do anything else), who (often, though not always) gets some kind of art education, and who then emerges as a professional artist who shows and sells work in a neatly prescribed cultural context. According to this institutional view, a work of art undergoes a process of validation and value creation by social consensus. The group charged with assigning the artwork its value in this tightly regulated system is made up of strategically placed institutions and individuals – the gatekeepers of the art world – who enjoy positions of power and authority. It also goes without saying that these institutions and individuals will only consecrate those artworks that subscribe to their own view of what art should be and which will not compromise their own positions of power or cause the downfall of the art world as it exists. According to the institutional view, artists are empowered by specific institutions and individuals who must allow

them into the “promised land,” “the land of greater possibility” of the art world. If the conditions are favorable, an artist’s work will become seen as sacrosanct and enter into the cultural Walhallas of our world. If the conditions are less favorable, however, the artist will be driven to question their own purpose in art making. The cultural topoi of “struggling artist” or “starving artist” have long been commonplace. Art historical narratives are replete with stories of struggle followed by consecration. Think of the story of Vincent van Gogh, for example. Stories like these are fueled by capitalism, as they often contribute to the economic system of value creation.

There is another view to be had according to which art is a more open and empowering system. Art as something that is accessible to all and something of which everyone is capable. After all, aren’t we all born with the ability to make marks on a piece of paper or to shape a piece of clay? Anyone who has ever observed a five-year-old child making art will recognize that this is art making in its purest form. The child is entirely absorbed by the moment, guided by instinct, without any apparatus of self-censorship at play. Art in this context is made for its own sake, for the sake self-expression. According to this view, art can be created by anyone, as artistic potential exists in each one of us.

Mysterious Beginnings: The Primeval Art Impulse

In 1940, one of the greatest discoveries of Paleolithic cave painting showing 1500 engraved wall figures and 600 painted animals, dated to ca. 15,000 BC, was made in Lascaux, near Montignac, France. This discovery completely changed our perception of what humans were capable of, and profoundly disrupted any sense of artistic superiority over our Paleolithic forebears. Moreover, this incredible discovery confirmed the idea that there was something essential and intrinsically human about art making.

There can be no certainty about why these cave paintings emerged or what function they

performed for the people who created them, though many theories have been proposed. One theory is that these images were intended as decorations. According to other theories, such as the “hunting magic” or “fertility magic” theories, the depictions of real creatures would favor their multiplication, creating a food source for hunters in the future. Another view is that the images are to be read on a symbolic level and that they hold shamanistic significance. In Lascaux, the cave’s only human figure, who has a bird’s head and erect phallus, and is involved in a hunting scene, has suggested to scholars that the human figure serves as a point of contact between the human and spirit worlds, a task usually performed by means of trances and hallucinatory experiences. Some scholars have drawn parallels between Paleolithic cave art and the visual evidence of shamanistic practices found in other locations, for example, on San rock art in South Africa (Lewis-Williams 1987).

While the origins of the first artistic human impulse are likely to forever remain a mystery, these early vestiges of human creativity are irrevocable evidence that art making is an essential human act that resides in a deep-set human need to reinvent and re-envision the world in which we live.

While we might not know much about why humans decided to represent the world, it is fascinating to observe the unity and coherence that characterizes many of these early representations that have survived. It is striking that we have examples of earthenware pottery dating back to the Prehistoric period that are decorated with organic or geometric motifs, suggesting that form and function were both seen as important in the production of the most innocuous of day-to-day objects. The painted pottery found at the sites of Samarra and Halaf in Mesopotamia (a. 6000–5000 BC) and the decorated pottery excavated in Cishan and Pelingang, China (ca. 7000–5000 BC) are two such early examples. One can also find evidence of strong decorative scheme in larger artifacts, such that elaborate wall paintings and modeled reliefs of Catal Höyük in central Anatolia (c. 6900–c. 6500 BC). Artifacts such as these, which historians associate with the

rise of agricultural and sedentary living, are striking for their sophisticated sense of design. The human capacity for the creation of visual design perhaps need not surprise us, as humans seem predisposed to respond to auditory stimuli such as rhythm and rhyme in spoken language, for example. Why would a similar predisposition not exist in the case of visual language as well?

The religious significance of early images produced by our ancestors continues to be a subject of debate in research among anthropologists, archeologists, and art historians. Contemporary art critic Jerry Saltz writes compellingly about the power of images, about the power of art as an amulet of supernatural significance: “for almost its entire history, art has been a verb, something that does things to or for you, that makes things happen. Holy relics in churches all over the world are said to heal. Art has been carried into war; made to protect us, curse a neighbor, kill someone; been an aid in getting pregnant or preventing pregnancy. There are huge, beautiful, multicolored, intricately structured Navajo sand paintings used in ceremonies to ask the gods for assistance. The eyes painted on Egyptian sarcophagi are not there for us to see; they are there so the interred person can watch. The paintings inside the tombs were meant to be seen only by beings in the afterlife” (Saltz 2018). Saltz’s emphasis that art can do something (as opposed to just be) can be traced back to the ideas of John Dewey, who had emphasized art’s role in enabling people to perceive, manipulate, or otherwise grapple with reality. Since the beginning, art has been used to infuse our life with imagination and possibility and connect us to another order or modality.

Gut-Grabbing Artifice

I have often heard it said that the visual arts are less accessible because their appeal is less visceral than say, words, or music. The visual arts are often seen as “too intellectual” or as involving too many barriers to interpretation. But just as frequently, the spectacle offered by art – especially by optical realism – can be equated with a powerful visceral experience too. We can all relate to the sense of

wonder produced while in contact with an example of unfathomable technical mastery, so much so that it makes us literally pause to take a breath. For me, this experience occurred when I came across a painting called *Three Rooms* (2000) by Christopher Gallego (Fig. 1) exhibited at Hirschl and Adler gallery in New York in 2001. I distinctly remember standing there dumbfounded, marveling at this phenomenal example of spatial illusionism. The three rooms of the title are represented *enfilade*, with one in the foreground, another in the middle ground, and the third in the background. It is almost as if this interior were a landscape divided into three horizontal bands, each of which is marked with a cylindrical object: a footstool, a cylindrical object, and a chair. The painting seems like a textbook example of both linear and atmospheric perspective. Linear because of the way the rooms and the doorways are arranged to create a sense of depth, and because of the way our eye travels “up” the floorboards towards the back of the room and horizon line. In the backroom, which is fuzzier because the artist was applying the rules of atmospheric perspective, we see a window through which we can see the indistinct greenery of a garden. Most of the space in the painting is devoted to representing the middle room, which is sparsely furnished with a table and two brocaded armchairs on either side. The blue cup on the table echoes the blue of the window frame in the backroom as well as the blue of the footstool in the front room, giving the whole painting a sense of harmony. I know of no other painter whose work elevates the prosaic aspects of daily life through a sensuous attention to color and surface detail.

Technical mastery over medium in the service of optical realism causes a sense of amazement in the viewer. In Western culture, an artist’s critical fortunes have traditionally been strongly connected with their particular ability to imitate empirical reality. Imitation (*mimesis*) was a prized quality that earned countless artists the accolades of their contemporaries. Among the many accounts of how artists earned the reputation of magicians or tricksters, perhaps the most iconic is Pliny, the elder’s account of the contest between

Possible in Visual Arts, Fig. 1 Christopher Gallego, *Interior with Three Rooms*, 2002, oil on canvas, 90 × 72 inches, New Britain Museum of American Art

Zeuxis and Parrhasios, according to which Zeuxis's grapes were rendered to such a degree of lifelike perfection that the birds themselves were fooled, and flocked down from the sky to peck at the painted fruit. According to Giorgio Vasari, Masaccio was the best painter of his generation because of his skill at imitating nature, recreating lifelike figures and movements as well as a convincing sense of three-dimensionality. "Vraisemblance" was also the life-long project of the eighteenth-century Swiss artist Jean-Etienne Liotard, who used the medium of pastel to capture the textures of skin, hair, and fabrics, such as silk, satin, velvet, and lace, as is exemplified in his portrait of Maria-Fredericke van Reede-Athlone (Fig. 2).

The invention of photography is generally thought of as a watershed that marks a time when the quest for *vraisemblance* became obsolete for artists. But optical realism continues to fascinate people today despite the existence of photography, largely because this form of art making has become rarer in the context of high-end

contemporary art exhibition venues (it is more commonplace at local or regional art fairs). While art academies in the beaux arts tradition continue to exist, they largely do so outside of Europe. The high-profile art schools in New York and London have by and large given up on optical realism as a learning outcome for their students, presumably because there is no market for it in the commercial field. And yet there are a great many working artists who labor in pursuit of this goal; examples include the painters Alan Lawson and Marie Thorndahl, and the sculptors Duane Hanson and Ron Mueck.

Participatory Viewing

Obviously, not all art is about representing the world that surrounds us according to the rules of optical realism. For a lot of artists, the accuracy of the depiction matters less than the process that goes into making the art, or the process that emerges from the viewing experience. This section considers the emotional and experiential potential of artworks that is made possible by the viewer's subjectivity.

From the perspective of many devoutly religious people, icons possess a special talismanic power because of the person they represent, but their divine character can also be explained through the spiritual process that the artist undergoes before creating the icon. The period of preparation involves a series of spiritual exercises (praying, fasting, etc.), which, once complete, allows for the act of creation, or rather "transcription" by the artist through divine intervention, to take place. The resulting image is believed to contain sacred, miraculous properties, according to Christian tradition, which can have a real impact on the devotee. The portrait of the saint is a stand-in for the real saint, not in the sense of physical likeness, but in the sense of true image of holiness that brings a life-saving belief.

Much secular portraiture can likewise be associated with the desired or perceived intention to capture the real "essence" of a person. Portraits of monarchs were venerated as surrogates of real

presence. Marriage portraits were presented as stand-ins for the real person, and miniature portraits of loved ones were worn as tokens of affection or mourning (Pointon 2001). Thus, there is a link that connects amulets worn by our ancestors, with portraits and relics of saints, to more secular forms of portraiture showing a beloved or even an object that serves as a stand-in for the beloved, such as a lock of hair.

To take this connection still further, one can draw a parallel between traveling for miles to a site of pilgrimage to see the relics of a saint, with a different kind of pilgrimage, which is cultural tourism. Think of the people flocking outside the Metropolitan Museum of art in the 1960s waiting in line to see the Mona Lisa. Museums – those repositories of cultural value – seem to have replaced cathedrals as sites of worship.

There are examples of artists active today who fulfill the role of spiritual healer of sorts. Among the most prominent of these is the performance artist Marina Abramovic, whose deeply personal projects aim to *elevante* and, ultimately, transform both herself and the viewer. Artworks can also rehabilitate an untold story of a person or a place. An example of such a project is Janet Cardiff and George Bures Miller's *Alter Bahnhof* video walk (2012), which was designed for the old train station in Kassel, Germany, as part of DOCUMENTA 13. During the 1940s this station was the departure point for a large number of Jews being shipped to concentration camps. The video takes the spectator for a walk through the station by means of voice prompts delivered via an iPod. The voice-over by Cardiff leads them through the building, providing instructions on the walk and commentary on personal experience and memories. An alternate world opens up where reality and fiction meld in a disturbing and uncanny way. The participants watch things unfold on the small screen but feel the presence of those events deeply because of being situated in the exact location where the footage was shot. As they follow the moving images (and try to frame them as if they were the camera operator), a strange confusion of realities occurs. In this confusion, the past and present conflate, and Cardiff and Miller guide us through a meditation

on memory and reveal the poignant moments of being alive and present.

Another artist who brings unresolved collective trauma and storytelling into his working process in the interest of rebuilding community is Krzysztof Wodiczko (b. 1943). His large-scale video projections in the urban space memorialize collective experiences of war (e.g., Hiroshima, 1999) or gender-based violence (e.g., his Tijuana Projection, 2001), among other topics. Wodiczko's projects are an oral history archive and memorial to the suffering endured by people who have become forgotten by history. His projections give a voice to people who have become disenfranchised and give the general public a means to be more aware of the process of history and the harmful impact it can have. His latest project, called *News*, is a collaboration with 12 refugees who have been resettled in the USA; their filmed likenesses and spoken narratives superimposed on a public historic monument of an unsung union hero of the civil war.

Artistic invitations to the public to engage with history can also have a more lighthearted and playful appeal. An example is Jeremy Deller's *Sacrilege*, a bouncy replica of Stonehenge created for the 2012 Olympic games. The piece invites the viewer to step into the installation and literally bounce in it, resulting in a sense of euphoria and surprise. This kind of artwork, which resembles a toy and likens the exhibition venue to a playground, might be formally far-removed from the icons that we were considering at the beginning of this section; still, what these works have in common is the intense emotional and physical response that a viewer might have as a result of engaging with the artwork.

The Rise of Individuality and Innovation in the Visual Arts

The power of the artist as a storyteller explains why artists have been recruited for centuries to work on behalf of state and religious institutions. One can argue that perhaps the greatest driver of possibility in the visual arts resides in the creation of idealized images of power, which aim to give a

Possible in Visual Arts, Fig. 2 Jean-Etienne Liotard, *Portrait of Maria Frederike van Reede-Athlone at Seven Years of Age*, ca. 1755–1756, pastel on vellum, Getty Museum of Art. https://commons.wikimedia.org/wiki/File:Jean-Étienne_Liotard_-_Portrait_of_Maria_Frederike_van_Reede-Athlone_at_Seven_Years_of_Age.jpg

group people the ability to define themselves through a visualization of their own identity and history.

In this context, one can think of vast architectural and sculptural ensembles such as the Apadana in Persepolis – an interior composed of 72 columns and monumental stairways, all of which were carved with hundreds of figures, all bringing tribute to the Persian king. These capture the glory of the Persian empire. Other examples of monumental artifacts used as a canvas for telling the story of the greatness of state include the column of Trajan (which depicts the war between the Romans and the Dacians ca. AD 100) and the Bayeux tapestry (which tells the story of the Norman invasion of England in 1066). Narrative cycles in Christian art – such as those by Giotto in the Scrovegni chapel (c. 1266) gave the majority of an illiterate population the possibility of accessing religious narratives for the purpose of collective and private worship.

Institutional propaganda machines of the visual kind continued to exist throughout seventeenth-, eighteenth-, and nineteenth-century Europe. A notable example is Peter Paul Rubens' *Marie de Medici cycle*, composed of 24 paintings commissioned in 1621, which illustrate the life of Marie de Medici and also pay tribute to Marie de Medici's exemplary qualities as a ruler.

While the nation-building role of art still plays an important role for art institutions today (also because it fuels funding), we are used to thinking about the visual arts as something that emerges out of an artist's subjectivity in the private arena of their studio.

When one thinks of the rise of individualism and subjectivity in the visual arts, at least in the context of Western art, one invariably thinks of the late eighteenth and early nineteenth centuries. It is a beguiling task to track the earliest visual manifestations of subjectivity during this era. Francisco Goya (b. 1746) is a fascinating example of an artist for whom there is a body of work that one associates with the artist's public persona – his royal portraits, for example – and another, much more private and mysterious body of work that seems to have produced out of the painter's deeply subjective and tormented visions. We also have a great many examples of highly idiosyncratic self-portraits that seem to be evidence of this era's highly introspective mood. There is a host of self-portraits where earnestness and self-scrutiny are staged in a manner that is alien to earlier portraiture, such as those created by Philipp Otto Runge, Asmus Jakob Carstens, Samuel Palmer (Rosenblum 1975), or Jean-Etienne Liotard (Bark 2008).

The twin concepts of artistic individuality and innovation have become commonplace when discussing the art from 1850s onwards. Art historians organize their narratives of art of the period from 1850 to 1950 around the concept of the "avant-garde," a term which refers to a group of people working in experimental, radical, or unorthodox ways. The attitudes of struggle and rebellion have come to punctuate the narratives of artists such as Gustave Courbet, Rosa Bonheur, Edouard Manet, Henri Matisse, Pablo Picasso, Andy Warhol, Jeff Koons, Damien

Hirst, etc. What gave rise to new possibility in the visual arts during the 1850s was the rise of the technologies of photography and film, which forced visual artists to come up with new ways for art to push the boundaries of representation. Much has been written about the moment when form (as opposed to content) became the main concern of artists. The way in which grappling with form became a way of reproducing the process of looking is illustrated by Cubism, for example.

Certainly, one of the things that twentieth-century art and narratives about it have brought to bear is the importance of form in the visual arts. It can be tricky to distinguish a beautiful subject, on the one hand, and a beautiful execution, on the other. Consider some of Francis Bacon's paintings, for example. Most people would consider his distorted self-portraits (e.g., *Self-portrait* of 1972) or figures posed in geometrical cages as pictures of horror and despair. But while the subject of his paintings can at first appear brutal and ugly, anyone who has seen Bacon's paintings in a museum would agree that there is nothing more beautiful and luminous than the way in which they are painted. There is much nuance and texture in Bacon's work, and one might wonder if the aesthetics of his brushwork serve as a kind of antithesis to his subject matter. Jenny Saville's work can also be interpreted in this way. Like Bacon, Saville is a masterful handler of oils who uses them to represent subjects that can be difficult to fathom. Her *Shadow Head* is a case in point.

The Move Towards Commodification, and Away from it

The history of art in the first half of the twentieth century is a favorite of students as the period is marked by a clearly identifiable linear progression characterized by a rapid success of different movements and -isms, each one responsible for its own definition of art.

Then came Marcel Duchamp's decision to call a mass-produced object "art." A rift just as momentous, which Arthur Danto would later associate with "the end of art," occurred when

Andy Warhol appropriated mass-produced and depersonalized objects such as a Brillo box or a Campbell's soup can, which he called art. At around the same time, Sol Lewitt declared that the artist's job was to come up with a template enabling anyone to make art. These rifts and all that they brought to bear on the art world are a lot more difficult for students to understand.

The art of today is no longer characterized by an -ism (except for perhaps pluralism). Today there are no more -isms, only individual artists.

During the 1990s, contemporary art became a hugely popular subject in the public media. Art has never been so global, nor has it ever been worth quite so much money, two phenomena that have prompted a proliferation of museums, galleries, foundations, and art fairs peddling art at the high, middle, and low ends of the market. The number of new collectors of art worldwide has exploded, and many of them have a very real impact on the creation of artists' careers and even art movements. An oft-named example of such a clouted individual is Charles Saatchi, who first made his name as an advertising executive and who became the patron of the "Young British Artists," who included artists like Damien Hirst the Chapman brothers, Mark Quinn, Marcus Harvey, Sarah Lucas, and Tracey Emin. The relatively quick rise to prominence of these artists thanks to one patron who caused a wave of patronage suggests that art history has never been made as quickly as it is today, and wealthy collectors are playing an important role in its making.

The narrative of contemporary art at the high end of the market has become familiar. Contemporary art has become a desirable way for the top 1% to invest their disposable income. At this level, the art world resembles the industries of real estate or private banking. A number of art dealers work as specialized brokers who are available to meet the needs of their clientele. An example is Larry Gagosian who opened his first gallery in Los Angeles in 1980. From 1989 to 1996, he co-owned a gallery in New York with the renowned dealer Leo Castelli, representing artists like Ellsworth Kelly, Roy Lichtenstein, and Bruce Nauman. After making some

spectacular sales (he famously sold a Mondrian for 12 million and a de Kooning for 137 million), today he represents leading international artists like Jeff Koons and Takashi Murakami, and owns 17 exhibition spaces worldwide. Gagosian has also started to collaborate with museums, providing instrumental support to many exhibitions and artist projects, including *Ceiling* by Cy Twombly in the *salle des bronzes* at the Musée du Louvre, a permanent commission that was unveiled to the public in 2010. Through initiatives such as this, there is a sense that high-end art galleries are in the process of monopolizing ever-larger sectors of the art market and the art world. The question is will this monopolization result in a homogenization of contemporary art production?

It is easy to look around at the commercial art landscape today and come away with an impression that art only exists as a commodity that serves the investment needs of high net worth individuals. Visit an art fair like Art Basel and there is a distinct sense that art has lost its accessibility. The kind of art one sees at these high-end fairs is heavily guarded and spectacularly priced. Whenever my students and I go to visit the fair as part of the current art class I teach, the takeaway is always a sense of incredulity. “How can an artwork cost that much?” seems to be all that anyone ever talks about on the train ride back home. A conversation that centers on price largely obliterates the conversation about the artwork itself.

There are a great many talented and under-represented artists out there, and it may seem unfair that many of them don’t get the critical and commercial attention that their talent seems to warrant. One of the most talented artists that I’ve come across far away from any cultural node is James Munce (b. 1938). Born and raised in Minnesota, Munce became a tenured professor at Kansas State University where he taught printmaking. He has gallery representation but deserves recognition that is far broader in scope. This begs the question, why aren’t art institutions doing more to support local artists?

A cure for one might call the “Art Basel” blues is to get involved with the art scene in your local town. Art studio visits make for a great opportunity to make such connections, as you get to speak with many different artists, each one of whom has an idiosyncratic way of seeing the world and making art. Every time I go to one of these events in Geneva or Lausanne, I come away with the impression that creativity in the visual arts is alive and well. Another way to get involved with the local art scene is to launch an art initiative. The Meet the Artist Lecture Series, which has hosted over 40 artists at Webster University, was created to support the local artist community.

²University of North Carolina, Charlotte, NC, USA

Abstract

Design means conceiving of objects or processes for accomplishing goals and it is a way to intentionally changing part of the world, as it is the case in prospective ergonomics. The design process usually requires creativity since designers have to propose objects or processes that are both new/novel – and possibly unexpected – and adapted to the design situation (e.g., useful and usable by future end-users). The goals of a particular design task and the intended functions of the design to be produced are not fully available at the outset. Thus, part of designing consists in constructing those goals and functions. It occurs as designing proceeds and it has the potential to alter what has been decided before, which makes designing non-monotonic across time. The cognitive processes and mechanisms involved in the creative design activities are of particular interest and are described in this entry as well as potential ways to favor creative design.

Definition and Importance of Creative Design

According to Herbert Simon (1995), well known for his work on the design sciences, “design [...] means conceiving of objects, processes or ideas for accomplishing goals, and showing how these

objects, processes or ideas can be realized” (p. 246). In the case of routine design (see Gero and Maher 1993), the product to be designed presents high similarities to previously developed products or services and the designer can adapt a predefined design frame or design solution to perform the design. In contrast, in non-routine or *creative design situations*, which are the focus of this entry, designers have to inject creativity in their design productions. Designing is particularly challenging when the designers have to reach creative design solutions or creative designs (see for instance, Bonnardel 2006/2012a, 2012b, Bonnardel 2021; Bonnardel and Bouchard 2017), which explains the special interest for studying creativity in design. In addition, creative design is increasingly important in our society, for several reasons:

- To be competitive, companies need to propose creative products or services since more and more users are looking for products or services that offer new functionalities.
- To contribute to the imagination and elaboration of future products (or services), as it is the case in prospective ergonomics (Robert and Brangier 2012), which aims at the creation of future products that have not yet been identified and leads designers to detect existing user needs and/or imagine and anticipate future ones.
- To open up new possibilities in various contexts, such as educational contexts, where creative design activities can play an important role in the teaching and training proposed to learners to develop their creative abilities (as well as their critical reasoning and collaborative competencies, in accordance with Organization for Economic Cooperation and Development - OECD’s recommendations) – and in the training proposed to future teachers (Bonnardel and Didier 2020; Didier and Bonnardel 2020).

Characteristics of Creative Design

Designers frequently have to face demands that could be, at a first glance, considered as

contradictory in the sense that they have to conceive objects (products or services) that are new while satisfying a variety of constraints, for instance in order to develop new products that will not destabilize future users. Many views on what makes a design creative point to the need that creative designs have to be novel, original, or new and useful, or functional or valuable (e.g., Christiaans 2002), as pointed out in definitions of creativity (cross-reference in the encyclopedia; Runco and Jaeger 2012; Weisberg et al. 2021). Thus, non-routine productions in design are dependent on the designers’ creativity, that is to say their “capacity to produce an idea that can be expressed under a viewable form or to realize a production [...], which is both new and unexpected, adapted to the situation and considered as having some value” (Bonnardel 2002, p. 95).

To point out specificities of creative design, we first highlight the fact that designers have to define characteristics of a product, process, or artefact, without having a predefined procedure to reach this design goal and while being provided with a limited set of requirements and ill specified objectives. Thus, the designer’s mental representation of the design problem is initially incomplete and imprecise and, depending on the authors, design problems have been qualified as “wicked,” “ill structured,” or “ill defined” problems (Eastman 1969; Reitman 1964; Rittel and Webber 1984; Simon 1973). The goals of a particular design task and the intended functions of the design to be produced being not fully available at the outset, a part of designing consists in constructing those goals and functions (which is called “problem finding”). It occurs as designing proceeds and it allows designers to complete their mental representations, and imagine, generate, and choose design options. Further, framing or situating those goals and functions within a particular view of the world has the potential to change them and possibly to alter what has been decided before. Thus, the dynamics of design problem-solving can be described as based on an opportunistic process (Visser 1994), which is in line with Dewey’s proposal that “subsequent experiences categorize and hence give meaning to what was experienced before” (quoted in Clancey 1997,

p. 94). Therefore, decisions previously taken can be changed by subsequent decisions and the meanings of decisions in the past can be modified by what happens in the present. The evolution of the designers' mental representations is also based on the development of "external representations" or intermediate objects (Bouchard et al. 2005), going from the first sketches to the final product or creative production. These external representations constitute a form of external memory and lead the designers to modify their perception and mental representation of the design problem (Bonnardel and Bouchard 2017; Goldschmidt 1991). Thus, designers can develop a "reflective conversation" with their sketches (Schön 1983), which allows them to develop a new understanding of the design problem. Therefore, designing is a non-monotonic temporal activity and each designer constructs and deals with his or her own design problem. In addition, a given design problem can admit a large number of possible solutions, which can be considered as more or less satisfactory, according to the constraints and criteria that are considered as important in the design situation (Bonnardel 2000; Rittel and Webber 1984).

Cognitive Processes and Mechanisms Underlying Design Activities

A Focus on Cognitive Processes

An ontology of designing, known as *Function-Behaviour-Structure (FBS)*, provides a framework to locate where the creativity can occur in designing (Gero 2000). It is based on three ontological categories: *Function (F)*, which corresponds to the intention of the designer, *Structure (S)*, which covers the elements and their relationships that go to make up a design, and *Behavior (B)*, which corresponds to the way the design works. As shown in Fig. 1, designers commence with *requirements (R)* from the client or future users, which express their needs and desires. During a process called *formulation* (process 1 in Fig. 1), designers transform requirements into functions and expected behaviors (*Be*), which correspond to a subset of possible behaviors for

the design product or solution. During a process called *synthesis*, designers transform the expected behaviors into structure (process 2 in Fig. 1). Then, in order to determine whether a structure satisfies the expected behaviors, designers analyze the behavior derived from structure – *Bs* (which is called *analysis*) and compare it to the expected behaviors – *Be* (which is called *evaluation*) – processes 3 and 4 on Fig. 1. If the results of that comparison are satisfactory, designers document the design in the form of an external representation – *D* (called *documentation* – process 5). When this comparison is unsatisfactory, then the structure, expected behavior, or the functions can be changed, which corresponds to a process called *reformulation* or *reframing* (reformulations I, II, III, respectively for *S*, *Be* and *F*).

The most common locus for studies on creativity is the processes allowing the generation of the product's structure (here called *synthesis*) and another common locus is the processes of reformulation or reframing.

Research in cognitive psychology and ergonomics allowed the analysis of designers' creative activities (Bonnardel 2006/2012a, 2012b; Bonnardel et al. 2018) and contributed to explore the evolution of designers' mental representations (e.g., during the formulation and reformulation of the design problem) in relationships with the generation and evaluation of creative ideas and solutions (during synthesis and evaluation), since these different processes are intertwined. For instance, the *A-CM – Analogy-making and Constraints Management* – model (Bonnardel 2000, 2006/2012a) highlights the role of two cognitive processes that can allow the designers to extend their space of ideas and to orient their decisions: analogy-making (which is described in the following section) and the management of various kinds of constraints. Taking into consideration constraints related to the design problem can contribute to both divergent thinking (e.g., when constraints lead the designers to look for ideas in a conceptual domain that is far from the design current area) and convergent thinking (e.g., when constraints are taken into account by the designers for assessing their ideas or solutions and progressively restricting the research space

Possible of Design, Fig. 1 The Function-Behavior-Structure (FBS) ontology of designing showing design processes (Gero 1990; Gero and Kannengiesser 2004)

Possible of Design,

Fig. 2 Spaces of creative, novel and routine designs (Gero 1990)

of design solutions until reaching a design that is both new and adapted to the situation). Constraints taken into account by designers can be *external*, for instance, when they reflect client's or future users' requirements (as described in the FBS ontology) and are provided in the design brief (*prescribed constraints*) or when they are induced by the human and technical environment (see Bonnardel and Lubart 2019). Other kinds of constraints can be considered as *internal* to the designers, when they are taken into account, consciously or not, during the creative activity and are specific to each designer (Bonnardel 2000, 2012a, b). These internal constraints can be dependent on each designer's experience, preferences, or personal background (*constructed constraints*) or they can result of an analysis of the current design situation (*deduced constraints*; see Bonnardel, *ibid.*). Constraints that are taken into account and managed by the designers can thus be related to the function, the structure, or the expected behavior of the design (Suwa et al. 2000).

Spaces of Possible Designs: Mechanisms of Change

To describe mechanisms allowing designers to reach creative designs, we propose to conceptualize designing as a space of possible designs resulting from the decisions the designer makes as he/she finds and frames the design problem. Within this design space, "routine" designs can be produced, which result of activities requiring little (or no) creativity. The remaining space can be occupied by "novel" designs, novel in the sense that they would be unlikely to be produced (Gero 1990). In addition to being novel, "creative" designs can be also unexpected or surprising when they sit outside the design space as originally conceived by the designer (see Fig. 2).

Several mechanisms can lead to changes in the space of designs and, thus, contribute to how a designer can produce creative designs. These mechanisms include analogy-making (as pointed out in the A-CM model), bisociation, concept removal, first principles, and creative destruction.

Possible of Design, Fig. 3a Changing the design space by substituting a concept from the original space with a concept from another space (analogy)

Analogy-Making Analogy is the process of transferring a concept from one design space into another design space and then substituting for a concept in the second design space. As a consequence, it changes the design space (Fig. 3a). An example of analogy would be when designing a lounge chair, finding that an overhead support served the same function as the legs of the chair, as it is the case in an artisanal swing, and substituting an overhead support for the legs in the new lounge chair (Fig. 3b).

Bisociation Bisociation refers to cases where concepts from two design spaces are joined together (Fig. 4a). An example of bisociation would be to take a chair and add the curved base of a baby's rocker cradle to produce a rocking chair (Fig. 4b). Another example would be to take a chair and add sensors that sense pressure points and uses the data they collect to change the shape of the chair to redistribute that pressure.

Concept Removal Instead of adding concepts to a design space, it is possible to remove a concept from the design space, changing it (Fig. 5a). An example of concept removal would be to take a chair and remove its legs producing a chair where the seat sat on the floor like an ottoman (Fig. 5b).

First Principles First principles designing involves commencing from an analysis of principles underlying the behaviors expected of the design (contrary to commencing with an existing design) (Fig. 6a). An example of designing a chair from first principles would be to look at the purpose of a chair as relieving the muscular activity of the back and legs supporting the torso when in a single position for a length of time. The spine is in its natural supporting position when it is vertical. When you bend your legs so your thighs are

Possible of Design, Fig. 3b Example based on analogy

horizontal, it bends your spine and requires additional muscle support. However, you can place your thighs at around 30 degrees to the horizontal and still keep your spine vertical. When you sit on a support in this position you slide forward, so you need support at your knees to stop this. Using this reasoning from first principles you create a new kind of chair (Fig. 6b).

Creative Destruction Joseph Schumpeter (1942) introduced the idea of creative destruction as the process by which one set of concepts completely displaces another set, rendering the initial set obsolete (Fig. 7a). When applied to creative design, this displacement changes the values used to produce and assess designs. As an example of creative destruction, we can look at landline phones up to 2006. The introduction of Apple's iPhone in 2007 shifted the values used to assess a phone to now include Internet interactivity, the function to play music, and the possibility to extend the capabilities of the phone through apps. None of these features existed previously in landline phones. Further price no longer was the primary determinant as phones can cost considerably more than computers. Today's smart phones are all marginal improvements on this first "creative destruction" 2007 iPhone (Fig. 7b) and landline phones have almost disappeared.

Possible of Design, Fig. 4a Creative design space produced by bisociation that adds concepts

Possible of Design, Fig. 4b Example based on bisociation

Possible of Design, Fig. 5a Changing a design space by removing concepts

Possible of Design, Fig. 7b Landline phone and the iPhone that displaced it

have been developed and it is even possible to lead designers to self-regulate their production of ideas through neurocognitive feed-back.

Classical Brainstorming Technique The seminal technique of brainstorming, created by Osborn (1963), aimed to help participants to generate and share ideas in groups to favor a “cross-fertilization” as well as to counteract their tendency to terminate the solution-generating process too early, through a two-step procedure distinguishing, on the one hand, the generation of ideas and, on the second hand, their assessment and selection.

Perspectives: Techniques and Tools to Expand the Creative Design Space

To complement our view of the possible of design, a focus of current research is on techniques and tools that can favor creativity. The general objective is to help designers to produce ideas and design solutions that are novel, unexpected, or surprising as well as adapted to the design situation. Such an objective can be reached through techniques and tools that can stimulate human’s reflection, for example, based on different kinds of brainstorming and/or human-computer interactions.

The Possible of Brainstorming Techniques

The most common technique to stimulate human’s reflection and evocation of ideas is classical “brainstorming”. Different variations of brainstorming

Variants of Brainstorming during Creative Design Variants of the brainstorming technique have been proposed and used in the design context. Thus, Jiménez-Narvæz and Gardoni (2014) reported several variants used as creative techniques in the early design process, such as *brainwriting* (when ideas are written down), *brainsketching* (when ideas are drawn), or *reverse brainstorming* (to analyze the causes of the problem). In addition, other variants were developed to favor brainstorming both in individual and collective situations as well as to lead designers to *focus not only on ideas but also on constraints related to the design problem* (Bonnardel and Didier 2016). Such variants of brainstorming were used and tested with different kinds of participants consisting in future designers and in future teachers specialized in creative activities (Bonnardel and Didier 2020). Based on these

studies, it appears desirable *to fit the brainstorming technique* to the participants' background and possibly to their personality traits (e.g., to favor divergent or convergent thinking depending on the participants' spontaneous tendency) as well to the design problem complexity.

Self-Regulation during Brainstorming Humans have the capacity to self-regulate, which is the process by which humans incorporate behavior change into their activities (Fig. 8). Although the mechanism of self-regulation is little known, it is possible to induce self-regulation in designers to improve their capacity to produce new ideas during brainstorming through neurocognitive feedback (Shealy et al. 2020). Typically, during brainstorming, the number of ideas reduces with time. Using a noninvasive method to measure a designer's brain activations while brainstorming, it is possible to present these brain activations in real time to the designers, along with instructions to maintain the level of activation that is shown to them graphically. Through self-regulation, the designer can maintain that level of activation and, in doing so, produces an increase in the number of ideas for a fixed time during brainstorming.

The Possible of Human-Computer Interactions in Creative Design

Tools can be categorized along a spectrum going from passive, through responsive, to active. Passive tools remain unchanged by their use (e.g., a spreadsheet). In contrast, responsive tools change along their use, and do

so by learning, in order to tailor their response to the user over time. Active tools interact with the designer since they respond to what the designer is doing, make proposals, and produce an iterative interaction. In a limited sense, we can consider that active tools potentially become "co-creators". Here are examples of such tools in the design context.

Expanding the Creative Design Space Through Human-Computer Interactions

Different kinds of systems can help designers in performing processes involved in the design activity, such as the TRENDS and SKIPPI systems, deep learning processes, critiquing systems (such as VDDE), and virtual dynamic personas.

For instance, the TRENDS system (Bouchard et al. 2008; Bonnardel and Zenasni 2010) allows designers to access to images showing preexisting objects in relationships with keywords that designers associate with the object to be designed (Fig. 9a). The images provided to designers are useful for mechanisms favoring the generation of new ideas, such as analogy-making, although the benefits of using such a system seem dependent on the users' level of expertise (Bonnardel and Bouchard 2011).

Another example of computational system helping designers to extend their research space of ideas is given by the SKIPPI system (Bonnardel and Bouchard 2017; Bonnardel and Zenasni 2010). This system allows designers to exploit relationships among words expressing, for instance, emotions and the value associated to the mark of the objects (Fig. 9b).

Possible of Design,

Fig. 8 The effect of self-regulation can be to expand the space of possible designs

**Possible of Design,
Fig. 9a** The TRENDS
system (source: www.trendsproject.org)

**Possible of Design,
Fig. 9b** The SKIPPI
system (source: www.skippiproject.com)

Such systems can *enrich the designers' research space of ideas* and, therefore, help them *to expand the creative design space*.

A complementary and promising way to expand the creative design space consists in using a *deep learning* process (a machine learning process in artificial intelligence), which makes use of neural networks (a computational technique modelled on human brain networks). What makes deep learning interesting is that it works with very large, unstructured, or partially structured data sets and generates structure from the data. In producing new structures for the data, it creates a space much larger than the space used to describe the original data set (Karimi et al. 2019; Quanz et al. 2019; Zhao et al. 2019). This increase in the space is what makes it

interesting in creative design, although its use in creative design is still nascent (Fig. 10).

An example of *responsive system* supporting designers' activities is provided by the critiquing system called VDDE – Voice Dialog Design Environment (Bonnardel and Zenasni 2010), which helps designers *to assess their own design solutions*. Toward this end, the system performs analyses in real-time, all along the design process, of external representations used by the designers to represent on the computational system the evolution of his/her design solution. Each time that a drawback is identified, the designer is provided with a critiquing message that points out the solution's weaknesses with regard to predefined constraints related to the design problem or by comparison with preexisting objects (when the new object to be designed has also to be in line

Possible of Design, Fig. 10 Deep learning expands the space used to structure a space of existing designs beyond the existing designs themselves

with preexisting ones to not destabilize users). In reaction to these messages, the designers can modify their design solution or explicitly decide not to modify it. In this last case, the designer introduces in the system new arguments, which makes the system evolve by extending its database.

Another new method based on interactions in a virtual space is called “*dynamic personas*” (Bonnardel et al. 2016; Bonnardel and Pichot 2020) and it allows designers to dynamically take into account users’ characteristics, expectations, and viewpoints. This user-centered design method allows, for instance, designers and ergonomists (represented by avatars) both to collaborate at distance on the same design problem and to interact in real time with an avatar that represents an archetypal future user. This method is derived of the classical “*personas*” method, which uses field data (gathered via interviews, observations and/or questionnaires) to construct “*personas*” corresponding to archetypes of users. In this classical (or “static”) method, personas are generally associated with concrete representations including both textual descriptions and photos. In contrast, in the “*dynamic personas*” method, information elements related to the user are provided dynamically to the designers and, possibly, other stakeholders. Studies on the impact of this last method on professional designers and students tend to show that it favors creativity, empathy, and collaboration, and, therefore, can promote designers’ creative and collaborative activities.

Conclusions

Apart from better understanding mechanisms that underlie creative design activities, the

major streams of thought in the early twenty-first century are related to developments offering complementary perspectives for favoring creativity in design (e.g., new techniques or interactive systems). Moreover, these techniques and systems should be adapted to designers’ characteristics, such as their level of expertise in a domain and their creative “profile,” including their background, personality traits, and their spontaneous thinking processes all along the creative design process (e.g., divergent vs convergent processes).

Some of these developments can be the result of advancements in artificial intelligence and neuroscience. Indeed, the increasing digitalization of activities has the potential to produce AIs (Artificial Intelligences) that go beyond just being responsive to human activity to moving towards becoming partners to humans while co-creating (Gero 2020; Lubart 2005). Deep learning when applied to languages has demonstrated that it is possible for an AI to carry out an interactive conversation with a human on topics that require significant knowledge (Radford et al. 2019), which is promising for developing dynamic personas based on autonomous conversational agents (Bonnardel and Pichot 2020). Deep learning has also the potential to change the relationship between databases of designs and their representations and, thus, provide access to hidden design patterns, which can then be used by an AI as co-creator companions to evoke human creativity (Karimi et al. 2020).

As more is learned about the brain and its relation to cognition and, in particular, to design cognition (Chrysikou and Gero 2020), this knowledge can be utilized to change the relationship of the brain and human activity. This change could be to

move from an unconscious relationship to a conscious one, where human behavior is directly affected by noninvasive interaction with the brain, as described above in the case of neurocognitive feedback (Shealy et al. 2020). Noninvasive brain stimulation interventions, such as transcranial direct current stimulation (tDCS) and transcranial alternating current stimulation (tACS), have been demonstrated to improve creativity (Chrysikou et al. 2017; Mayseless and Shamay-Tsoory 2015). This approach has not yet been applied to designers to determine whether it improves their creativity.

Therefore, possibility of design are various and associated to promising perspectives for better understanding and favoring creativity in design.

Possible Worlds

Michael De

Department of Philosophy, Utrecht University,
Utrecht, The Netherlands

Abstract

Possible worlds have become important in analyses of modal or intensional notions such as necessity and possibility. In this entry we will

look at (i) the importance of possible worlds analyses, (ii) two ontological accounts of possible worlds, and (iii) two important applications of possible worlds to conditionals and truth in fiction.

Keywords

Possible worlds · Ersatzism · Modal realism · Counterfactual · Truth in fiction

Introduction

There are many kinds of possibilities. For instance, when I say that it's possible that I left my keys in my jacket pocket, I mean something like the following: it's compatible with my evidence that my keys are in my jacket pocket. I am expressing an *epistemic* possibility. However, when I say that I could have had a different name, I am not expressing anything about my epistemic state: I know what my name is because my evidence rules out the possibility of my having a different name. What I am expressing might be called a *metaphysical* possibility. Even though these senses of possibility are quite different, they can be given a unified semantic analysis in terms of *possible worlds*. To say that it is possible that ϕ is to say that ϕ is true in some possible world. For instance, to say that it's possible that I left my keys in my jacket pocket is to say that it's true in some world – i.e., *that is compatible with my evidence* – that my keys are in my jacket pocket. And to say that I could have had a different name is to say that it's true in some world *simpliciter* that I have a different name. Indeed, as we will discuss in more detail later, a great many senses of possibility can be given a semantic analysis in terms of possible worlds. This is one of the main reasons that the topic of possible world has garnered considerable interest since the mid-twentieth century.

The main application of possible worlds is to the (often semantic) analysis of *modals*. To keep matters simple, let us focus on propositional operators, i.e., operators that apply to a proposition to yield a proposition. A modal operator is an expression that qualifies the truth-value of a

proposition. For instance, it is not just true that two and two is four, it is *necessary*. The expression “it is necessary that” expresses that a proposition is not just true as a matter of fact, but that it couldn't be false, i.e., that it is true in all worlds (of a given class). This is an important feature that only some propositions have, and most propositions of interest in philosophy, mathematics, and science are precisely of this kind.

Modals are typically *intensional*. An operator is intensional just in case the truth-value of a proposition with the modal as its main connective cannot in general be determined by the truth-value of its arguments. The conjunction we learn about in introductory logic class is truth-functional since the truth value of a logical conjunction is a function of the value of its conjuncts. However, consider “Cats have fewer toes on their hind paws” and “Two and two are four.” They have the same truth-value, and yet appending “Necessarily” to each yields propositions differing in truth-value. Thus, “necessarily” is intensional. The same goes for “*S* knows/believes/desires that,” “It ought to be the case that,” “It is provable that,” “It is obvious that,” “It was the case,” and so on. A natural question now arises: if the truth-value of a modal proposition cannot in general be determined by the truth-value of its parts, how can we determine the truth-value of a modal proposition? This is one, if not *the*, main application of possible worlds, i.e., to the semantic analysis of intensional expressions.

The remainder of this entry will provide an overview of possible worlds semantics (§[Unified semantic analysis](#)), some general features of possible worlds (§[General features of possible worlds](#)), two main accounts of possible worlds (§[Two accounts of possible worlds](#)), and two important applications in philosophy of possible worlds semantics (§[Two applications of possible worlds](#)).

Unified Semantic Analysis

As we noted earlier, many modals can be given a unified semantic analysis in terms of restricted quantification over possible worlds. A typical

semantic analysis of, respectively, a “universal modality” $\Box$ and an “existential modality” $\Diamond$, runs as follows:

- ($\Box$) $\Box\phi$ is true at a world w iff ϕ is true at *all* worlds u possible relative to w ;
 ($\Diamond$) $\Diamond\phi$ is true at a world w iff ϕ is true at *some* world u possible relative to w .

It is important to note here that possibility is (or at least may be) a *relative* matter: what is possible relative to one world need not be possible relative to another. The case in which every world is possible relative to every other is a limiting case. For instance, under an epistemic reading of the modal, what is possible relative to a world w will depend on what possibilities are ruled out by one’s evidence at w , and different possibilities are ruled out by different bodies of evidence.

If we compare the statement that ϕ is possible with the statement that ϕ is true in some world possible relative to our own, the latter seems less intuitive and more difficult to understand. One may then wonder how possible worlds are supposed to furnish an *analysis* of modality. Much of the success of possible worlds can be attributed to what might be called extensional “reduction.” Prior to possible worlds analyses, figuring out the inferential role, i.e., the logic, of modals was mostly left to intuition. We know that truth entails possibility, but does the possibility of the possibility of ϕ entail the possibility of ϕ ? Until we have some way of analyzing possibility using traditional extensional tools, it is difficult to answer questions like this. However, given ($\Diamond$), we can now say that the possibility of the possibility of ϕ is true at a world w just in case for some world u possible relative to w , there is a world v possible relative to u at which ϕ is true. Thus, the possibility of the possibility of ϕ entails the possibility of ϕ just in case relative possibility is transitive. The question then comes down to whether relative possibility is transitive, and in some cases this is a much easier question to answer than the one we started with concerning the entailment involving iterated possibilities. For metaphysical modality, for instance, every world should be possible relative to every other, in which case relative possibility is indeed transitive.

So one of the main virtue of possible worlds semantics is that it gives us an extensional way of (semantically) analyzing intensional notions. Important questions, then, concern the philosophical foundations of possible worlds analyses. What are possible worlds? How do we have epistemic access to them? Does a relative notion of possibility make sense? Should possibility be taken as irreducibly intensional? These are some important questions that possible worlds semantics raises. In the next section, we will characterize possible worlds in a very general way. We will then go on to consider two main accounts of possible worlds, as well as two applications of possible worlds to the analyses of conditionals and truth in fiction.

General Features of Possible Worlds

Our world is home to everything.¹ Other possible worlds are supposed to be like this as well, at least in how they represent things to be. This maximality of worlds entails:

Completeness For every proposition ϕ and world w , either ϕ is true at w or else false at w .²

In other words, possible worlds decide the truth-value of every proposition, and this allows us to say whether a proposition is necessary or not.

Though most assume that possible worlds are complete, most possibilities intuitively conceived are not. For instance, the possibility that I roll a one on my next die toss does not settle the truth-value of every proposition. There are numerous ways in which I could realize rolling a one, so features extrinsic to the roll are not settled. Mundane talk of possibilities in this sense is non-maximal. They are more like *situations* in

¹If there are abstract objects, such as numbers and propositions, then perhaps they are not *part* of our world in the usual sense. Nonetheless, every concrete object is part of our world.

²I am ignoring systematic failures of completeness, such as might be caused by vagueness, non-denoting terms, etc.

situation semantics: that is, they are ways *parts* of worlds might be.³ Nonetheless, an incomplete possibility can be viewed as, not a single world, but a class of worlds, viz., the worlds at which the possibility obtains. Then say that a proposition is true at the class iff it is true at each member and otherwise it fails to have a truth value. Classes of worlds may then be viewed as situations. However, as most of the philosophical literature identifies possibilities with worlds, we will not consider incomplete possibilities any further.

Possible worlds are so called because they are *possible*. Thus, one other important feature they have is that they are *metaphysically* (and not just logically) consistent:

Consistency For every proposition ϕ and every world w , if ψ and ϕ are metaphysically inconsistent, then ϕ and ψ are never both true at w (at the same time).

Using metaphysical consistency to characterize worlds introduces two problems. First, what counts as metaphysically consistent is debatable. Some, for instance, think that one could not have had different origins, e.g., parents, a thesis known as *origin essentialism*. What counts as logically consistent is of course also debatable, but much less so. Moreover, the notion of logical consistency is amodal, and it is not clear whether metaphysical necessity can be given a similarly amodal analysis, in which case no *reductive* analysis can *characterize* a world in terms of Consistency, even if every world must satisfy it.

What other general features possible worlds have is more or less up for grabs. Some hold, for instance, that something must exist at every possible world.⁴ Others think that exactly the same things exist at every world.⁵ Some of these debates boil down to what worlds are, ontologically speaking, a topic to which we now turn.

Two Accounts of Possible Worlds

What is a possible world? Given the role that possible worlds play, it should be no surprise that there are many accounts that posit entities well suited to play that role, with each having their own advantages and disadvantages. In this section we will consider two accounts, one being fairly ontologically innocent and the other fairly controversial.

Linguistic Ersatzism

We noted that possible worlds are both complete and consistent. One obvious candidate to play the role of a world, then, is a complete and consistent set of sentences. Such sets provide for a straightforward notion of representation, according to which a possible world represents that it is the case that, or makes true that, ϕ just in case ϕ is a member of the world. In other words, a world implicitly represents that something is the case iff it explicitly does.⁶ Ersatz worlds are real and exist, but they are abstract. What more could we want?

For one, it looks like it will have to take as primitive or brute that some sentences are jointly metaphysically inconsistent, and by doing so a potentially important motivation for employing worlds is undermined, viz., to provide a *reductive* analysis of possibility. Most ersatzists are not much bothered by this, however, since it is not part of the ersatzist program as most conceive it to provide *reductive* analyses. This is a primary aim of modal realism, a competitor view which we'll come to shortly. What possible worlds provide, according to the ersatzist, is a means of furnishing a unified semantic analysis of modals, which may

P

³ See (Barwise and Perry 1983).

⁴ See e.g. (Lewis 1986).

⁵ See, e.g., (Linsky and Zalta 1994).

⁶ A world could be complete in another sense that would complicate the notion of representation. It could contain enough sentences to *imply* for any sentence that either it is true at the world or else false there, so that sentences not explicit members of the world would be *implicitly* represented as being true or false there. For instance, a world might be a collection of sentences including (i) which fundamental particles exist, where they are located, and what properties they have, and (ii) postulates stipulating how to get the macro-truths from the micro-truths.

be best accomplished via quantification over worlds (versus primitive modal operators).

Another problem for ersatzism concerns the “worldmaking” language, i.e., the vocabulary from which the sentences that make up worlds is formed. Obviously, it cannot be ambiguous and each sentence must be able to receive a determinate truth-value. So the language cannot be a natural language like English, though it could be some cleaned-up and idealized natural language, whatever that may be. It must also include a name for each individual and each space-time region since there are possibilities concerning each such individual and region. Since there are uncountably many such regions, the language will be larger than your typical language, but that in itself need not present an obstacle.

Now supposing the ersatzist has found a suitable worldmaking language, there is still a problem about having predicates for alien properties, if there be. An alien property is any property that is not definable by even infinitary means from the properties instantiated at our world. They are completely foreign to our world. If there are alien properties, and it seems intuitively compelling that there could be, the ersatzist won’t have the linguistic resources to express modal truths concerning them. The ersatzist analysis will then fall short of being able to account for all possibilities.

One possible way out is to argue that such properties can be *described* in our language via their nomological roles. For instance, we can say that there is a property having such and such features that is distinct from any property actually instantiated and is not definable from any property actually instantiated. It would be good enough to say that there is an alien property playing such and such a role. However, we now run into a problem. If properties do not have their nomological roles essentially, i.e., if *quidditism* is true and two properties could swap their nomological roles, then this strategy of describing alien properties will conflate distinct possibilities. It will not be able to say that there are two worlds w and u instantiating properties playing the same roles, except that two properties having certain roles in w have swapped those roles in u . Whether this is a

genuine challenge depends on whether quidditism is true and whether the ersatzist can account for quiddistic possibilities.⁷

Linguistic ersatzism is an attractive account of possible worlds for several reasons. First, sets of sentences are ontologically acceptable entities by most non-nominalists. Second, representation can be given a straightforward analysis in terms of set-theoretic membership. Third, it makes nearly no additional assumptions about worlds besides consistency and completeness. However, it also has several drawbacks. First, it arguably fails to provide a reductive account of modality, and second, it is unclear whether it can account for all possibilities. We will see that there is room for improvement on these two fronts, but not without cost.

Modal Realism

David Lewis is the founding father of *modal realism*, the view that there are other possible worlds that are, ontologically speaking, much like our own.⁸ Other worlds are unified spacetimes occupied by concrete objects. Specifically, Lewis takes a world to be a maximal mereological sum of spatiotemporally related objects, maximal in the sense that if anything is spatiotemporally related to part of a world, then it too is part of the world. This entails that nothing in distinct worlds is spatiotemporally, and hence causally, related, and therefore that worlds never share a common part. This means that nothing literally exists in more than one world, even though a world can *represent* concerning an individual that it exist there and have certain properties. How a world does this by means of similarity: a world w represents concerning an actual object o that it has property F just in case there exists something o' at w that (i) sufficiently resembles o and (ii) has property F . If such an o' exists it is called a *counterpart* of o .

This makes intuitive sense. When I want to skip a stone over the pond, I choose stones on the basis of their similarity to previous stones that

⁷See (Lewis 1986, §3.2) for a discussion of this challenge to the ersatzist, and (Sider 2002) for a solution.

⁸See (Lewis 1986).

skipped well. I know that if one stone sufficiently resembles another that skipped well (i.e., it has a flat bottom, etc.), it too should skip well (ignoring any failure of my own to properly throw). So we can and do gain knowledge of capacities and possibilities by means of similarity. That is at least how some modal *knowledge* is grounded. It is of course another thing to say that that is how modal *truth* is grounded, as the modal realist holds.

It may seem incredible to believe in genuine possible worlds and, moreover, to believe that there are enough to furnish an adequate theory of modality. After all, it does not follow from the mere existence of other possible worlds that there are enough of them, i.e., at least one for each maximal possibility. Nor does it follow that even if there were enough of them, that modal truth is grounded in them. The first problem Lewis solves by maintaining a thesis called the *principle of plenitude*, which holds that for any way a world could be, some world is. This principle can be given bite when understood as a *principle of recombination*, which states roughly that anything can coexist with anything else, or that any parts of worlds can be “patched” together. Lewis claims that this gives us enough possible worlds to account for all possibilities.⁹ It is not clear how Lewis answers the second problem, but if he is right that possible worlds are indispensable to our best analyses of certain modal notions including out best analysis of modality, then it is a small abductive step to the conclusion that modal truth is grounded in possible worlds.

Two Applications of Possible Worlds

Conditionals

A conditional is, roughly, an “if... then” statement. In English there are at least two types of conditionals, the indicative, e.g., “If Oswald didn’t shoot Kennedy, someone else did” and the subjunctive or counterfactual, e.g., “If Oswald

hadn’t shot Kennedy, someone else *would have*.” Clearly the examples differ: the indicative is true and the counterfactual false. If Oswald hadn’t shot Kennedy, we’ve no reason to think anyone else would have.

Clearly the two-valued material conditional we learn in logic class cannot capture the counterfactual since any material conditional with a false antecedent is true. Moreover, we know that the counterfactual is intensional. A now popular analysis, due to Lewis and Robert Stalnaker, employs possible worlds.¹⁰ The simplest version of the analysis runs as follows:

- “If ϕ were the case, ψ would be the case” is true at world w relative to context c iff in all the worlds u most similar to w as determined by context c , if ϕ is true at u , ψ is true at u .

This analysis does a fairly good job at capturing the natural language counterfactual, but it’s not perfect. For instance, it makes vacuously true any antecedent with an impossible antecedent. For instance, “If two and two were five, two and two would be four” comes out true on the analysis, which many have found counterintuitive.

The notion of comparative similarity between worlds (i.e., w is more similar to u than v is) employed in the semantics is ingenious, and does a compelling job of capturing the context-sensitivity of the counterfactual as well as notions that are amenable to a counterfactual analysis. As we will see, something like it is also employed in Lewis’s account of truth in fiction. The notion of a “most similar” or “nearby” possible world is often invoked in discussions on the analysis of knowledge. For instance, Duncan Pritchard endorses the following version of the so-called safety principle:

Safety If S knows a contingent proposition ϕ , then, in nearly all nearby possible worlds in which S forms the belief that ϕ in the same way as in the actual world, ϕ is true.¹¹

⁹He moreover gives a sort of indispensability argument for believing in other worlds in the first place.

¹⁰See (Lewis 1973b) and (Stalnaker 1968).

¹¹See, e.g., (Pritchard 2005).

What counts as a nearby world depends on which worlds are closer to ours than others. This has now become a common metaphor in philosophy, e.g., when discussing whether a counterfactual is true.

In the literature one can find counterfactual analyses abound. For instance, such analyses have been given for causation¹² and dispositions.¹³

Truth in Fiction

A work of fiction makes true some sentences and not others (assuming fictions are consistent). Moreover, we want to say that some sentences not explicitly stated in the fiction are nonetheless true in the fiction. For instance, we want to say it's true that Holmes lived in the northern hemisphere because that is entailed by his living in London. Indeed, when we think about what is true in a fiction, we tend to hold certain background facts fixed. We assume that it is true in the Holmes stories that London is in the northern hemisphere, even though nowhere in the fiction is that made explicit.

There are several analyses of truth in fiction, but Lewis' fits the current theme since it employs a notion of comparative similarity among worlds. According to Lewis, a sentence such as "Holmes lives on Baker Street" should be read as having an implicit fiction operator prefixed to it: "In the fiction f , Holmes lives on Baker Street." The question now arises as to how we should analyze the operator "In the fiction f ." Lewis proposes two analyses, the simplest of which is the following:

- A sentence of the form "In the fiction f , ϕ " is non-vacuously true iff some world where f is told as known fact and ϕ is true differs less from our world, on balance, than does any world where f is told as known fact but ϕ is not true.¹⁴

This analysis can be read counterfactually: "In the fiction f , ϕ " is non-vacuously true iff were f told as known fact, ϕ would be true. Given that a world in which London is in the northern hemisphere is more similar to our world than one in which it isn't, this analysis gives us that is true in the Holmes stories that Holmes lives in the northern hemisphere. Indeed, it may hold too many of the background facts fixed that may conflict with what is intuitively true in the fiction. This is why Lewis considers a related analysis where the background depends on the doxastic states of the agents of the world in which the fiction is told as known fact.¹⁵

Here again we see the fruitfulness of possible worlds, and specifically the notion of comparative similarity among them, to a compelling analysis of a fairly elusive notion like truth in fiction.

Summary

We have seen the importance of possible worlds analyses of a wide range of notions, including necessity, counterfactuals, and truth in fiction, but we have also seen some of the limitations and complications that such analyses raise. For instance, what exactly are possible worlds, and if they are not modally reducible, do they genuinely clarify notions to which possible worlds analyses are put? These are important questions that become increasingly important as possible worlds analyses continue to flourish.

Post-Truth

Abstract

This entry examines the phenomenon of post-truth in its relation to the notion of the possible. It starts by outlining the roots and main characteristics of the post-truth context, including its relation to politics, social media, and post-modernist assumptions about the relativity of truth. While the spread of falsehoods and lies is not uncommon across the history of society, what makes the current trend particularly alarming is the fact that we are dealing with more than distortions of what is true; we are witnessing a growing disregard, in the case of some individuals and groups, of reality itself. To overcome the pitfalls of relativist accounts, what we need is a recognition of the fact that the possible is not the opposite of the real but its ever-present companion. And, also, that cultivating possibilities, including in the form of “possible truths,” should be guided by ethical question about what these truths “do” for self, others, and society.

Keywords

Post-truth · Misinformation · Post-modernism · Relativism · Possible · Ethics

The current debate on post-truth has a lot to tell us about the possible. On the one hand, this association might sound surprising as the two have widely different connotations: highly negative in case of post-truth, commonly associated with the rapid deterioration of democracy and the dismantling of social consensus, and generally positive about the possible, usually connected to human striving and human ways of being in the world. On the other hand, both these notions raise important questions about the nature of reality and, in particular, the relation between what exists in the mind vis-à-vis what exists in the world.

In some ways, post-truth societies opt for inhabiting possible rather than actual worlds, they prefer fiction to fact and, most importantly, position their own fictions as facts. They are, thus, effectively making some possibilities real while ignoring unwanted realities. This process is central for many possibility-enabling phenomena discussed within the present encyclopedia, from play and imagination to utopian forms of thinking. And yet, at the same time, there is a fundamental distinction between a post-truth mentality and a playful one, for instance. This difference comes from the fact that the possible and real are not opposed to each other but inter-dependent. And it is precisely this inter-dependence that is challenged by post-truth beliefs and practices. In the end, analyzing more closely the reality of post-truth invites us to reflect much more deeply on the ethics of possibility, a topic I return to toward the end.

In *The Origins of Totalitarianism*, Hannah Arendt wrote that “the ideal subject of totalitarian rule is not the convinced Nazi or the convinced Communist, but people for whom the distinction between fact and fiction (i.e., the reality of experience) and the distinction between true and false (i.e., the standards of thought) no longer exist” (Arendt 1958, p. 474). This is a chilling reflection for our times, marked by what many call post-truth politics or “the triumph of the visceral over the rational, the deceptively simple over the honestly complex” (D’Anconda 2017, p. 20). Politicians, corporations, and journalists stand accused of fomenting this alarming trend by showing little concern for objectivity in their support for

populist and nationalist policies. And yet, this is much more than a political issue – it is also an epistemological one, a question of what we consider to be truthful knowledge and of our ability to know ourselves, others, and the world we live in. Such interrogations have a long history in philosophy and, for the most part, they served the purpose of helping us reflect on the (im)possibilities associated with the human condition. But in today's social and political climate, they became weaponized by extreme groups who tend to share one or more of other beliefs such as anti-science, anti-vax, climate change denial, and white supremacy, among others.

The Era of Post-Truth

The term post-truth has an interesting history (for more details, see D'Anconda 2017). It is believed that the term was first used in a 1992 article written for the *Nation* by Steve Tesich. He decried in that article the fact that the American public, traumatized by Watergate and other scandals, not only started turning away from the truth but suppressing it. Moreover, as Tesich noted, they had decided this freely, not because of some external totalitarian pressure. The notion rose to prominence many years later, in 2016, in the context of the double shock of the “Brexit” referendum in UK and Donald Trump's election in the USA. It was that year that post-truth became Oxford Dictionaries' Word of the Year after its usage surged by 2000% (McIntyre 2018).

But what exactly is post-truth and does it mean a total disregard for the truth? More than this, is this a new phenomenon, specific for early twenty-first century or one that goes back to twentieth century propaganda and perhaps even further? When we are lamenting the fact that we live now in a post-truth world, aren't we forgetting perhaps that we have lived this way all along?

In trying to define post-truth it is best to start from the notion of truth. For centuries, at least since the times of Aristotle, deciding what is true has been a relatively straightforward affair. This was made easier by Aristotle's early definition: “To say of what is that it is not, or of what is not that it is, is

false, while to say of what is that it is, and of what is not that it is not, is true” (in Baggini 2017, p. 4). Such an understanding of truth substantiates the correspondence theory or the belief that a high degree of correspondence should be established between statements about the world and facts of the world. The more statements diverge from facts, the further we get from gaining (or stating) true knowledge. This conception has been attacked across the centuries both by philosophers who didn't believe we can “objectively” grasp reality and those who saw language as polyphonic, thus making our statement about the world impossible to be reduced to a one-to-one type of correspondence. But, even when challenging the basis of an “objective” truth, the concern for it remained. In contrast, in recent decades, “objectivity – or even the idea that people can aspire toward ascertaining the best available truth – has been falling out of favour” (Kakutani 2018, p. 17). Beyond a contestation of what counts as fact, we notice more and more a disregard for facts.

Why Post-Truth? Why Now?

The Oxford Dictionaries definition of post-truth states that it designates a climate in which objective facts are less influential in shaping public opinion than appeals to emotion and personal belief. This doesn't mean, however, that we don't care anymore about truth claims but that they start to be subordinated to political points of view (McIntyre 2018, p. 11), to how we want to see the world rather than how it is. This is not a question of misperception or the creativity of language, as post-modern thinkers would have us believe. It is a bold reversal of power in which the possible (e.g., imagined events and facts) dominates the real or, at least, what people perceive as real. The possibility that a political viewpoint is just as good and truthful as any other – more than this, that my views are better than yours, despite any need to critically reflect on evidence – has become the new normal, at least for specific groups.

For some, this is a sure sign of a global trend. This trend “is a crash in the value of truth,

comparable with the crash of a currency or a stock” (D’Anconda 2017, p. 8). For others, speaking of post-truth societies is “premature and misguided,” “we wouldn’t even be talking about post-truth if we didn’t think truth mattered. The world is neither ready, nor willing to say goodbye to truth, even in politics where it sometimes seems as though it has already taken its leave” (Baggini 2017, pp. 6–7). The “truth,” as always, is somewhere in the middle.

More specifically, we need to make some important distinctions in this area (see McIntyre 2018). First, we should distinguish between falsehoods and lies. The former are unintentional mistakes, the latter refer to deliberate ways of covering up the truth. Then we have wilful ignorance whenever we don’t know if what we say is true, but we say it anyway. In other words, we don’t bother to know if what we are saying is indeed correct, often out of laziness. This gets us closer to what the philosopher Harry Frankfurt referred to as “bullshit” (see Frankfurt 2005), which is different than lying. When lying, the person needs to have a clear understanding of what is true, in order to conceal it. When bullshitting, he or she demonstrates only a careless indifference toward knowing what is actually true. From here on there is just one more step to self-deception and delusion in which we get to convince ourselves that a falsehood is, in fact, the truth, even when all credible sources dispute this conclusion. This is much closer to what specialists discuss as post-truth: the conviction that what one thinks and especially how one feels can change a lie into something truthful.

All the phenomena above – uttering falsehoods, lying, bullshitting, deceiving ourselves – are not new and have been part of human history since its beginning. Either for cognitive reasons (related to how we perceive and process information) or social ones (related to how group membership changes our thinking), we have always dwelled, to some extent, in the realm of heightened possibility that is post-truth. But the difference today is that not only individuals do this – entire communities engage in such practices as well. Even more alarming, some politicians take part in this. As McIntyre (2018, p. 10) shrewdly

notes, and as we could see from Donald Trump’s presidency and Boris Johnson’s premiership, “when our leaders – or a plurality of our society – are in denial over basic facts, the consequences can be world shattering”.

From History to Fiction

We established, above, that today’s current social and political climate is both similar and different than other historical times. This means, among other things, that we can and should learn from the past, including past works of fiction, in order to know more about the mechanisms of post-truth politics and, perhaps, find more effective ways to counter them. In the words of D’Anconda:

Lying has been an integral part of politics since early humans arranged themselves in tribes. Anthropologists note the importance of deception in primitive societies, especially, but not exclusively, when dealing with outsiders. Plato ascribed to Socrates the notion of the ‘noble lie’—a myth that inspires social harmony and civic devotion. In Chapter XVIII of *The Prince*, Machiavelli urges the ruler to be ‘a great pretenders and dissembler’ (D’Anconda 2017, p. 23).

This reality has often been dramatized by novelists with a taste for the dystopian and for constructing (almost) perfect totalitarian worlds. As mentioned earlier, it was the grim experience of Nazi, fascist, and communist propaganda that inspired many of these authors to explore the processes underpinning post-truth politics and to dissect its main features. George Orwell stands out among novelists in this regard for offering us, with his well-known book, *1984*, a great example of how politics, power, and technology can collaborate in rendering any notion of truth useless. At first sight, there aren’t many parallels between the dystopian universe of *1984* and our world today, the former designed and controlled by the Party, down to every detail of one’s life, including mental life, the latter marked by fragmentation, mobility, and interconnectivity. And yet, some commonalities can be found. Take, for instance, the role played by technology. In his piece of fiction, technology is used to monitor and dominate individuals while, in our (real)

world, it has the power to bring people together and increase participation, including in online spaces. But, a closer look at the Internet and, in particular, social media and their impact of the spread of post-truth mindsets and ideologies quickly comes to show that technology remains “the all-important, primary, indispensable engine of post-truth” (D’Anconda 2017, p. 49). The use of algorithms to expose people to content they are likely to want and believe in, the emergence of “echo chambers,” and the general ease with which conspiracy theories spread online are as disturbing as Orwell’s view of total control.

Perhaps one of the most direct anticipation of today’s discussion of post-truth transpires in 1984 in the notion of “doublethink” or the power to hold two contradictory beliefs in one’s mind at the same time, and trust that both of them are true. It is by controlling language, especially simplifying it, that people in Orwell’s dystopia become incapable of questioning the reality imposed by the Party and are trained, from early on, into accepting whatever the Party wants to be true, even when this constantly changes. Today’s simplified use of language on social media, often reduced to abbreviations, hashtags, and the use of emojis, could be interpreted as signs of cognitive impoverishment, at least in some online spaces. And yet, the power of the Party went beyond language and was ultimately expressed in how the mind and body of dissidents were subjected to torture at the hands of interrogators. The famous scene in which Inner Party member O’Brien tells his victim, Winston Smith, that reality exists in the human mind, and nowhere else, is emblematic for the methods of those who spread misinformation online. In 1984, however, the Party was supposed to hold the ultimate truth. Today we are more likely to be persuaded that there is no such thing. The outcome is the same though: more openness to manipulation and a generalized sense of resignation.

Fiction itself, even when presumably about the future or alternative worlds, is rooted in history. In this case, it is interesting to note that George Orwell was not a passive bystander to the major world events taking place during his lifetime, most notably World War II. A participant in the

Spanish civil war, he was terrified by the ability of Fascist propaganda to shape people’s perception of the Russian intervention in the conflict. This prompted him, in his 1942 essay called *Looking Back on the Spanish War*, to reflect on the strange feeling that “the very concept of objective truth is fading out of the world” (see D’Anconda 2017, pp. 3–5). The fact that lies can pass into history and, effectively, become history, made Orwell wonder about how the story of the war will be written if Franco remains in power and even if he doesn’t (given the fact that his government kept traces of only those narratives that served its purposes). Most interestingly, his main concern was not that history is biased – this is very much a fact of living in a human society – but that few people of his time showed interest in correcting such biases. That, in the end, they lacked the belief that history could be written truthfully... The endless possibilities of (re)imagining history had no anchor in reality, they would only serve as mirrors of individual and collective intentions, hopes, and fears. Who was to be blamed for setting up those mirrors? Many people, both then and now, but one group seems to stand out, at least for how unexpected (even for its own members) their contribution is to post-truth.

Blaming Post-Modernism

It is rare to have philosophers and other academics (partially) accused of societal upheaval and yet this charge is often repeated by those who analyze post-truth. In brief, besides the political and technological dimensions of this phenomenon, there is a clear epistemological underpinning to the debate. Epistemology concerns the theory of knowledge used by scientists, philosophers, and lay people alike to make truth claims and, as such, ideas such as “there is no ultimate truth about the world” and “truth is a matter of perspective, my truth being just as good as yours” are epistemological in nature. They are typically associated with relativism which itself is associated with post-modernism and its related manifestations (e.g., social constructionism). As a current of thought that swept across the social sciences and

humanities in late twentieth century, post-modernism offered a much-needed counterpoint to positivist science with its essentialism, reification and, oftentimes, justification of social inequality. In response, post-modernist thinkers claimed that there was no single privileged position from which to understand reality and, as such, inclusive and critical dialogues between perspectives were needed in order to grasp the world as it appears to the multiple participants in society. This view, for as modern (or rather, post-modern) as it might sound, has an illustrious past in philosophy and science, versions of it being promoted, at different times, by thinkers as varied as Gorgias, Protagoras, Plato, Descartes, Hobbes, Darwin, Nietzsche, William James, Michel Foucault, and Richard Rorty, among others (Blackburn 2006). While it is hard to do justice to the diversity of these philosophical views, overall, the post-modern position promotes:

the idea that there was a right or wrong answer to what a text (whether written or behavioral) ‘meant’ was thrown into question. Indeed, the notion of truth itself was now under scrutiny, for one had to recognize that in the act of deconstruction, the critic was bringing his or her own values, history, and assumptions to the interpretation as well. This meant that there could be many answers, rather than just one, for any deconstruction. The postmodernist approach is one in which everything is questioned and little is taken at face value. There is no right answer, only narrative (McIntyre 2018, p. 125).

This way of framing post-modernism brings it close to current sociocultural theories of the possible (see Glăveanu 2020), theories that discuss this phenomenon with the help of notions like difference, multiplicity, perspectives, and dialogue. However, it is on the topic of relativism that post-modernism and sociocultural theory split, in particular when the latter is grounded in pragmatism. This is because, as critics of post-modern views argue, there is a difference between saying that knowledge depends on one’s position and perspective and that reality itself is relative to one’s position and perspective. The first standpoint acknowledges the fact that our understanding of the world depends to a large extent on who we are and where we are in this world, but it doesn’t deny

the possibility of grasping reality through the coordination of multiple perspectives. In contrast, the second standpoint makes any attempts at grasping reality futile and shatters it into a multitude of isolated and solipsistic perspectives.

What is interesting to notice when it comes to the current debate about post-truth is the paradox at the heart of relativism. When it was first proposed, in mid to late twentieth century, its aim was social, political, and emancipatory. In particular, post-modern thinkers wanted to give voice to the marginalized and oppressed and to challenge the hegemony of the powerful (e.g., white, male, rich, Western), including their hegemony on truth. It was an effort to increase pluralism within society and contribute to calls for diversity, inclusivity, and civil rights. In early twenty-first century, however, almost the same arguments about truth are being paraded, especially by (far) right politicians and commentators, in order to promote misinformation, squash resistance and, more generally, suppress voting rights and increase social inequality (McIntyre 2018). This is all done through the simple act of questioning obvious facts. If everything is a “social convention,” D’Anconda (2017, p. 92) asks, “what is to stop the purveyor of ‘fake news’ from claiming to be a digital desperado, fighting the wicked ‘hegemony’ of the mainstream media?”

It is by using the epistemological means of post-modernism that creationists, for example, argue that children should also learn in school about “intelligent design” or anti-vax supporters and climate change deniers claim that their experience and beliefs should be as important as those of scientists. “Teach both sides” or “teach the controversy” (Kakutani 2018) are calls often heard today, ignoring how deeply unequal the evidence for each side is. Controversies are created where there arguably should be none. And this displays, once more, the perverse power of post-truth propaganda to appropriate the means of post-modern thinkers and, to some extent, of those who are concerned with how the possible is envisioned and enacted in society. One great example of this is doubt, a key practice fueling the post-modern drive to deconstruct language and criticize power. But, also, an enormously potent weapon in the assault on truth we have been witnessing for many decades. In their seminar book,

Merchants of Doubt, Oreskes and Conway (2011) document how the tobacco industry fought against scientific consensus around the negative consequences of smoking for health. By setting up the Tobacco Industry Research Committee in 1954, these corporations wanted not to deny the role of science but cultivate doubt about scientific consensus. They aimed, and to a large extent succeeded, to pit a few fringe, questionable figures, against the scientific establishment and foster confusion about what might actually be the case. Even if the Committee has been disbanded following a series of lawsuits across the USA, this post-modern and, in essence, possibility-enhancing practice of doubt was extended to climate change where it continues to be relatively effective, at least for some. In the words of D’Anconda, again:

[...] the normal practice of adversarial debate is [nowadays] morphing into an unhealthy relativism, in which the epistemological chase is not only better than the catch – but all that matters. The point is simply to keep the argument going, to ensure that it never reaches a conclusion (D’Anconda 2017, p. 46).

The Ethics of Possibility

There are lessons to be learned about the possible from considering the case of post-truth, namely, the fact that unconstrained possibility often has negative consequences for individuals and society. In this context, without a set of criteria for what passes as “truth” we are left with the daunting possibility that everything could be true, a situation that renders the notion hollow. This, in turn, opens the door for extreme forms of relativism, skepticism, and apathy to take over and reduce the prospect of building common ground and engaging in collective action. On the other hand, sociocultural and pragmatist studies of the possible hold the key to sidestepping some of the most negative implications of post-modernism while harnessing its power to question hegemonic relations and structures. To achieve this, we need to engage with the possible not only as an ontological and epistemological category but an ethical one. The question of ethics is intrinsically related to debates about post-truth, for example, in the double standards adopted by people who “routinely embrace an obscenely high standard of doubt toward facts that they don’t want to believe,

alongside complete credulity toward any facts that fit with their agenda” (McIntyre 2018, p. 11). But, at a deeper level, this question is about the consequences of spreading misinformation for other people and society as a whole. In the end, our capacity to create new possibilities and go against “what is” doesn’t mean that we should do so without considering what our explorations of the possible mean for others.

Summary

When it comes to the notion of truth, we need to collectively find a way to “defend the plurivocality, ambiguity and non-programmability of truth while also defending the right to say that some things are not just different, they’re wrong, and this without embracing the no less mistaken idea of absolutism” (Caputo 2016, p. 9). And the first step toward reinstating truth is to understand its complexity and the fact that no easy definition would do. As Baggini (2017, pp. 8–9) notes, “truths can be and often are difficult to understand, discover, explain, verify” but “they are also disturbingly easy to hide, distort, abuse or twist.” Our responsibility, as scholars of possibility, is to examine the implications of any “possible” truth in the world and what it affords human action and interaction. It is not only the case, in this regard, that basing one’s beliefs and choices on misinformation or falsehoods ends in failure. What matters most is what any given position and perspective helps us do or achieve, in a pragmatic sense. “Truths” that lead to oppression, discrimination, and exclusion are, ultimately, possibilities not worth exploring. The ethics of the possible invites us to consider possibility as interdependent with what is real and not a separate category; together, they substantiate the joint reality we experience and try to improve with, for, and toward others (Glăveanu 2018).

Potential

Giovanni Emanuele Corazza
DEI-Marconi Institute for Creativity, University of Bologna, Bologna, Italy
LAPEA, Université de Paris, Boulogne-Billancourt, France
LAPEA, IFSTTAR, University Gustave Eiffel, Versailles, France

Abstract

In this entry, the notion of potential is first introduced in its general meaning and then discussed for its role in creativity studies. In particular, by introducing the dynamic definition of creativity (Corazza, Creat Res J 28:258–267, 2016), which foresees that creativity is a context-embedded phenomenon requiring potential originality and effectiveness, this term becomes a central actor in the understanding of the complex creativity

phenomenon in all its multiple nuances. In order to cover all the important dimensions in creativity studies, three classification frameworks are used: the 4P's by Rhodes (Phi Delta Kappan 42:305–310, 1961), the 5A's by Glăveanu (Rev Gen Psychol 17:69, 2013), and the 4C's by Kaufman and Beghetto (Rev Gen Psychol 13:1, 2009). Exploiting these perspectives, 16 different forms of creative potential are introduced and discussed: individual creative potential, embedded individual creative potential, mini-c creative potential, little-c creative potential, Pro-c creative potential, Big-C creative potential, systemic process potential, embedded process potential, universal process potential, instantaneous product potential, experiential product potential, condensation potential, cultural evolution potential, socio-cultural context potential, action potential, and virtual world potential. These relevant forms of potential in the creative process interact in various ways to determine the overall level of potential originality and effectiveness in a creativity episode.

Keywords

Potential · Creativity · Dynamic definition of creativity · Creative potential

Defining Potential

The word *potential* comes from the Latin adjective *potis*, carrying two different meanings: capable or possible. Whereas *capable* normally refers to an individual who can perform an action or achieve an objective, *possible* is a wider category that can be associated to inanimate or animate entities, inserted in different natural, technological, or socio-cultural environments of different complexity, up to a cosmological meaning: the potential of the universe in terms of its possible courses of evolution. The eighteenth century had to come before the term potential started to be used also in its noun form, in association with the growing knowledge and fascination for electromagnetism, wherein the electrical potential is intended as a measurable physical entity associated to a quantity of accumulated charge. If the

charge is statically accumulated over an isolated capacitor nothing happens, but there is a latent potential for a (larger and larger) current as determined by loading the capacitor with (smaller and smaller) values of resistance. This physical notion became later a metaphor to describe human potential as a latent characteristic that may or may not be translated into actual realization depending on contextual conditions, which might favor or stifle its development. In the modern Merriam-Webster dictionary, potential is defined both as an adjective and as a noun. In the former case, the meaning is: “existing in possibility: capable of development into actuality”; as a noun, potential is defined as “something that can develop or become actual.” As can be seen, in both cases the term potential entails a mental projection onto the future through forecast, foresight, or anticipation (Corazza 2017a; Poli 2011).

Potential in Creativity

The notion of potential acquires a fundamental role in the realm of creativity studies. In fact, the term potential in its noun form finds a place inside the definition of creativity itself. The dynamic definition of creativity (Corazza 2016) posits that “creativity requires a *potential* for originality and effectiveness.” In Corazza and Lubart (2020, 2021), an extension of this definition is presented, which puts into evidence the fundamental role of situation: “creativity is a context-embedded phenomenon requiring *potential* originality and effectiveness.” Originality and effectiveness are classic requirements for a creative achievement, as reflected by the standard definition of creativity (Runco and Jaeger 2012): on the one hand, creativity entails originality, that is, the co-existence of novelty, nonobviousness, and authenticity (Corazza 2016). However, originality is not sufficient: at the same time, there must be a form of value, utility, appropriateness, and meaningfulness with respect to the concerned domain, all of which is covered by the effectiveness term.

The introduction of the term potential inside the definition of creativity serves to make a clear and fundamental distinction between creativity

and creative achievement. Indeed, the recognition of originality and effectiveness in a creative process cannot be intended as a static or objective assessment, but it is a dynamic and subjective act that can change over time, space, or culture. And this potential for recognition is embedded into a sociocultural context. Many examples can be brought as evidence to support this observation of the dynamic nature of creative assessment, but a most eminent one shall suffice here. Most of the discoveries and inventions by Leonardo da Vinci were not considered, understood, nor actualized in his time. Leonardo anticipated by hundreds of years the principles of anatomy, optics, geology, and hydrogeology, as well as the concepts of the tank, of the helicopter, of underwater exploration, and the list could continue. All these ideas, at the time of Leonardo, could not be considered as creative achievements, as their effectiveness was not recognized nor altogether comprehended. But given that Leonardo can arguably be considered the most creative person in the entire history of *homo sapiens*, being creative does not necessarily require creative achievement here and now, but only a *potential* for it. In other words, a very creative person holds a very high potential for originality and effectiveness, because he/she challenges the state-of-the-art, avoiding taking shared knowledge for granted, and produces visionary ideas. Quite often this activity does not lead to immediate recognition: this is a state that is identified as *creative inconclusiveness*, indeed a very important part of the creative process. To be creative, when the state of creative inconclusiveness is elicited, one must show resistance to frustration, strong determination, and self-belief in oneself as a creator.

Beyond the distinction between creative achievement and creative inconclusiveness in creativity, there is a second fundamental consequence of introducing the concept of potential inside the definition of creativity. The extraction of value from the outcomes of the process, which determines whether one is met with achievement or inconclusiveness, cannot be simply considered to be resolved as the activity of a judge or a board of judges. A judge would know what is right and what is wrong, what is creative in a domain, and

what is not. But the real value of a creative idea will only be seen *a-posteriori*, in the future, and no one can express definitive judgment about a yet unknown future. Therefore, the person interacting with the outcomes of a creative process should be thought of as an *estimator*, dynamically expressing reactions which might even lead to refinement of the ideas under consideration. The potential in a dynamic creative process is therefore the result of the interaction between all the actors involved in the process, the thinker(s), as well as the estimator(s).

Forms of Potential in the Creative Process

Given that creativity implies the existence of a potential for originality and effectiveness, it is important to understand where and in what form this potential can be observed. Following the lines presented in Corazza and Glăveanu (2020), it is useful to address this question by considering three of the most influential frameworks in creativity studies. Namely, the 4P's model by Rhodes (1961), including Person, Process, Product, and Press; the 5A's model by Glăveanu (2013), including Actor, Action, Artifact, Audience, Affordance; and the 4C's model by Kaufman and Beghetto (2009), encompassing mini-c, little-c, Pro-c, and Big-C forms of creativity. It should be clear that these dimensions are not mutually orthogonal; rather, they suggest different but partially overlapping points of view, as well as useful taxonomies, in addressing the nuances of the creativity phenomenon. Each of these strands in creativity studies has been shown to be the home of a different kind of potential (Corazza and Glăveanu 2020).

Individual/Person/Actor Creative Potential

The individual is perhaps the more natural starting point in the search for the meaning of potential in creativity. This dimension corresponds to the Person (4P's model) or the Actor (5A's model).

Indeed, the *individual creative potential* is the most classic understanding for potential in creativity studies, and its purpose is conventionally that of predicting whether an individual will be able to produce and enjoy creative success in a near or far future. Thus, this notion is typically tied to measurement techniques, which can be based on the production of small creative products (e.g., a short story, a drawing) and/or on the measurement of important resources such as divergent thinking (e.g., performance in an Alternative Uses Task). A test battery designed for the measurement of individual creative potential has been introduced in (Lubart et al. 2013). Studies have also been performed to determine the biological neural correlates to individual creative potential (for an overview, see Mastria et al. 2018).

However, a potential for future creative achievements is not at all a guarantee: potential can remain latent, it can be stifled or stimulated by the experiences in one's educational trajectory and, later, professional trajectories. The development of potential is always a bio-cultural process. Following Glăveanu (2013), the Actor or Person is always embedded in a field of social relations, and creativity is shaped by the surrounding socio-cultural context (Corazza and Lubart 2021). Therefore, the potential for originality and effectiveness of the Actor is also embedded and strongly influenced by context: given the same individual, his/her potential will change depending on the environment. We identify this form as the *embedded individual creative potential*. To measure one's embedded individual potential, it is not sufficient to use questionnaires, reports, or laboratory tests: it is necessary to include also direct observations in the field. The relevance of this indication comes from the fact that the creative potential of an Actor might change considerably when measured in a lab vs. observed in natural, everyday life environments.

Considering now the 4C's model by Kaufman and Beghetto (2009), the individual potential takes on four quite different, and more specific, nuances. Starting from mini-c creativity, this involves the personal epiphanies one experiences when discovering new ideas, new things,

new heuristics, etc. Every human being, even in the presence of severe pathologies, has a potential for these experiences, which we identify as the *mini-c creative potential*. The expression and growth of the mini-c creative potential is fundamentally influenced by early developmental experiences in life, as well as the entire trajectory in education. The design of education systems that provide useful stimuli in this sense is a critical and urgent issue, as well as the identification of new methodologies for the observation of dynamic interaction in a classroom, such as microlongitudinal studies (Beghetto and Karwowski 2019).

Considering a developed adolescent or an adult, little-c activities include hobbies, non-professional, or everyday creative endeavors. Depending on openness to experience, curiosity, and personal motivation, a form of *little-c creative potential* can therefore be identified. The larger this potential, the more likely an individual is to engage in nonprofessional vocational activities, which sometimes can be very important for one's well-being and freedom of expression. Indeed, it might appear that little-c creativity is a purely optional activity for an individual, far from being a necessity. However, when the concept of "organic creativity" is introduced (Corazza 2017b), defined as those conditions, attitudes, and actions that bear the potential to be at the same time productive in socio-economic terms and conducive to human well-being, it becomes clear that what is at stake is nothing less than human happiness (Csikszentmihalyi 1997). Adopting a socio-political perspective, it appears that policies and institutions introduced in our society play an important role in generating the conditions that allow citizens to conduct existences in which there are sufficient possibilities for engaging in creative activities, at least at the little-c level. The increasing average age in our societies, along with longer periods of retirement, shorter working weeks, as well as the growing introduction of anthropomorphic and non-anthropomorphic forms of artificial intelligence, are all factors that point to the growing importance of favoring the population's little-c creative potential as a policy.

Further, it is important to address the Pro-c levels of creativity, pertaining to professional creativity and innovation endeavors. When Guilford delivered his famous speech on creativity at the APA conference in the middle of the twentieth century (Guilford 1950), advocating the urgent need for psychologists to study this fascinating construct also in view of dramatic socio-political changes after World War II, he certainly had in mind as a target the development of the *Pro-c creative potential* for the American population. The aim was that of empowering industry and commerce with a potential for continuous innovation, leading to the outstanding progress that transformed the Industrial Society into the current Information Society. Unfortunately, for many decades this potential was not coupled with a sensitivity for the sustainability of the industrial progress and the preservation of natural resources and of the environment in general. In the first half of the twenty-first century, we are witnessing the dramatic effects of this oversight, and we are in urgent need for redirecting the power of the *Pro-c creative potential* of our populations to include ethical and sustainability values along with performance and economic values.

Finally, it is necessary to conclude this section on individual creative potential by considering Big-C creativity, that is, its most eminent form. This was in fact the starting point for creativity studies when Galton (1869) began to observe possible hereditary schemes with the families of geniuses. Undoubtedly, it would be too ambitious and unrealistic to predict Big-C creativity; therefore, *Big-C creative potential* is typically observed in hindsight, by searching for the conditions that led a person in a specific time epoch to produce ideas and artifacts that changed the course of development of the arts, science, or technology (Albert 1983; Eysenck 1995).

Process/Action Creative Potential

A creative process is a complex system, involving several diversified resources in terms of available time, available relevant information, level of

expertise in the domain, level of expertise in creativity, available materials, organizational factors, social factors, the adopted strategies, the challenges to be faced, etc. (Corazza and Agnoli 2015). The overall ensemble of these resources generates a new form of potential, identified as *systemic process potential*. As an example, the level of the challenge has a critical influence on the originality and effectiveness that could be achieved through systemic process potential. This can be immediately realized if one compares the potential of writing a short essay with respect to a book. The potential for originality and effectiveness is much larger in the second case, because of a change not in the individual creative potential, but in systemic process potential. As a second reflection, consider the fact that systemic process potential depends on the resources and institutions available in a specified socio-economic environment. This is the reason why we expect certain innovations to come from specific parts of the world and not others. Systemic process potential is therefore heavily affected by both intrinsic and extrinsic constraints; while the former can be modified by the Person/Actor, the latter are usually beyond our control.

A Process/Action always contains a dialogue between several Persons/Actors, some directly involved and some only marginally, but each one contributing to the richness of the embedding sociocultural framework. The more intense the dialogue, the higher the creative potential. Therefore, an *embedded process potential* can be defined, which depends fundamentally on the levels of dynamic collaboration and co-creation. For example, in the case of a co-creation episode involving two Persons/Actors, the embedded process potential of the ensuing Process/Action will be very different from the simple sum of the individual creative potential of the two separate Actors: their complex interaction can afford the emergence of unpredictable trajectories. This does not always bear a positive effect: depending on interpersonal dynamics, co-creation can also become very troublesome and negative, so that the embedded process potential of this episode could also be lower than either of the two separate individual potentials.

On the other hand, it is impossible for a creative process to produce an isolated episode. All creativity episodes are concatenated, as humans cannot create ex-nihilo. The notion of process can therefore be extended to the Dynamic Universal Creativity Process (DUCP; Corazza 2019), which encompasses four layers of complexity: material, biological, psycho-social, and artificial. The DUCP provides a framework of explanation for the evolution of our cosmos since its inception (Corazza and Lubart 2020), and this view is in line with the cosmology of Alfred North Whitehead, as delineated in his Process Philosophy. Now, it should be clear that not all parts of the universe are evolving at the same pace: therefore, the notion of *universal process potential* can be introduced to indicate the potential of a specific creativity episode as a function of its position within the DUCP. For example, if new materials are brought back from the exploration of Mars surface, then a creativity episode in the domain of material science will enjoy a higher universal process potential.

Product/Artifact Creative Potential

It is very interesting to note that once a Product takes form as the outcome of a creative process, it begins to live a life of its own, which often transcends the creative Person, and that enjoys several forms of potential to produce an experience of originality and effectiveness in those that come to interact with it. The first distinction to be made is between Products that are consumed in real-time (e.g., a live performance, a ballet, music improvisation) and those long-lasting Products that remain available through time, and whose impact is mainly measured in the future (paintings, sculptures, innovations in products and services, scientific theories, etc.). On the other hand, even a real-time Product can leave a long-lasting trace in our episodic memory, if the experience has left the Audience in awe. Therefore, for real-time Products we can introduce an *instantaneous product potential* (which will be larger depending on the intended originality of the performance with respect to other existing

styles, as well as on its supposed effectiveness), but also an *experiential product potential*, representing the potential for a long-term effect in the memory of the Audience.

Considering long-lasting Products, the notion of *condensation potential* can be introduced. As defined in Jackson and Messick (1964), “condensation” is a characteristic of Products that do not reveal all their essence upon first experience, that are future oriented, that we seek to re-examine and re-experience over and over. A fitting example could be represented by Bernini’s sculptures in Villa Borghese (Roma, Italy), characterized by a level of breathtaking beauty so high that it is possible to enjoy them over and over across the years without ever feeling that their condensation potential is exhausted. Moreover, if the condensation potential of a Product is high, even if it is not well received at the time of its output from the creativity episode, the experience and the consequent assessment can be turned upside down later (perhaps even centuries later, see the above discussion on Leonardo da Vinci). As an example, the paintings by Vincent Van Gogh were completely neglected during the painter’s life, but they had a large condensation potential, which only after several tens of years from the painter’s death passed from a latent to an explicit state.

Finally, adopting the 5A’s model to refer to Products as “Artifacts” gives evidence of their nature as elements of culture, as well as to the cumulative growth of human culture in the course of our evolution as a species. From this perspective, the instantaneous product potential, experiential product potential, and condensation potential of an Artifact should be assessed in terms of the contribution that the Artifact can give to the evolution of human culture, yielding a fourth form identified as *cultural evolution potential* of a Product. This does not always correspond to a positive effect. A couple of examples are in order, starting from a negative one. An invention with a very high experiential potential could have in the end a very low cultural evolution potential if, at the same time, another invention is generated with a higher potential for immediate effectiveness. So, competition in a domain

produces dynamics in the potential of Artifacts. On the other hand, in the 1970s, a standard technology for glass production suddenly became a cutting-edge technology when optical fibers were invented (Cattani 2006), providing an example of latent cultural evolution potential that became explicit when the opportunity arose.

Press/Audience/Affordance Creative Potential

It is finally possible to focus the attention of the characteristics of the Press, the environment, the Audience, and the provided Affordances without necessarily instantiating a creativity episode. This means that an environment itself can be endowed with various forms of creative potential, which will then interact with individual, process, and product potentials. Three forms of potential associated to this dimension can be envisaged: the *sociocultural context potential*, the *action potential*, and the *virtual world potential*.

The sociocultural context potential descends from the fact that changing situational elements can have very significant effects on a creativity episode and its potential for originality and effectiveness. When studying creativity, performing an experiment in a “neutral” laboratory setting vs. creating the conditions for the introduction of real-world situational variables can change the results of experiments. For example, Kimmelmeier and Walton (2016) have shown that women outperform men in originality when the focus area involves providing benefits to others, but this effect disappears when an element of threat is added to the environment. These results are not only interesting, but they also significantly differ from the generally accepted notion that there are no gender differences in creativity (Baer and Kaufman 2008), providing evidence of the existence of a gender-dependent sociocultural context potential.

On the other hand, the *action potential* descends from material culture (Corazza and Glăveanu 2020) and is a characteristic of the affordances in the surrounding environment. The action potential grows larger for larger

possibilities of use and interaction with material entities. Imagination can be used to enlarge the set of possible affordances, which means that individual creative potential interacts with action potential.

To complete this section, it is important to turn the attention to the fact that new information and communication technologies (Corazza et al. 2010; Feather 2013) give the possibility to create virtual worlds, and these artificial environments can embed creative processes, in which the Actors can be represented as themselves or through the mediation of an avatar. How these virtual environments affect the creative process is still a largely open question, but we can immediately introduce the notion of *virtual world potential*, which encompasses the effects of these new forms of social interaction, as well as the digital affordances of virtual objects. The impact of these artificial elements on the creative process is being studied (e.g., Guegan et al. 2017), and the results appear to be promising.

Conclusions

This entry is focused on showing the reader that the concept of potential is a fundamental element in creativity studies. In fact, the dynamic definition of creativity foresees that creativity is a context-embedded phenomenon requiring a potential for originality and effectiveness. By considering the 4P's, 5A's, and 4C's models for creativity studies, it is possible to introduce sixteen different forms of potential, which are reported here for convenience:

- Under the Person/Actor dimension: individual creative potential, embedded individual creative potential, mini-c creative potential, little-c creative potential, Pro-c creative potential, and Big-C creative potential
- Under the Process/Action dimension: systemic process potential, embedded process potential, and universal process potential
- Under the Product/Artifact dimension: instantaneous product potential, experiential product

potential, condensation potential, and cultural evolution potential

- Under the Press/Audience/Affordance dimension: sociocultural context potential, action potential, and virtual world potential

It is important to note that these different forms of potential are characterized by strong mutual interactions, and the study of these interactions is still an open question for scientific research.

Potential images · Potentiality · The possible · Visual ambiguity · Accidental images · Creativity · Play

Definition

“Potential images” is a term coined by art historian Dario Gamboni to designate a specific category of ambiguous, indeterminate images. Their ambiguity creates new potentialities for stimulating the spectator’s imaginative, perceptual response, as opposed to purporting to convey furthering determined perceptions and interpretations (Gamboni, 2002, p. 8).

Introduction

This entry will present some theoretical frames and empirical cases and modes associated with the operation of potentiality of image from a historical perspective, especially to demonstrate the fruitfulness of using “accidental” images and imaginative perception for the invention of pictorial subjects. This specific dimension of the artistic process reveals the playful side of creativity. Other

theoretical positions in art history and the philosophy of culture reveal new modes of instantiation of the potentiality of image. Apart from the ambiguity of image, the indeterminacy of image as discussed by Gottfried Boehm (Boehm, 2002) – as opposed to determination (sharpness) of image – reveals itself as a quality of image; the “productivity of the lack” (due to the indeterminacy of image) creates an *iconic difference*, that is, the fundamental *possibility* of differentiation between images and non-images. Similarly, the disruption of the determinism in the image, defined by Oliver Grau as *immersion* (Grau, 2003), based on the impossibility of distinction between images and non-images, draws the observer into virtual reality. Immersive images create a new potential dimension of reality that has become undistinctive in relation to its original reality.

An important part of this entry is devoted to the potentiality of image rooted in the very conception of a work of art itself, the act of creation. This theoretical position is advocated by a handful of art historians, such as Henri Focillon, Aby Warburg, and Hans Belting, as well as philosophers like Henri Bergson and Giorgio Agamben. On different voices and various theoretical registers, they sustain the same idea: an unforeseeable novelty and potentiality do exist in the world, and the most poignant examples are to be found in the realm of the arts. This anti-determinist position rejects art-historical explanations that try to account for the evolution of artistic form exclusively through contextual factors and that deny any possibility of free will; instead, human

freedom is reflected in human creativity as a source of potentiality of image beyond determination. This entry will place these ideas into a dialogue with Focillon’s theory of art, nourished by the philosophy of Henri Bergson, and finally move onto the theory of potentiality developed by Giorgio Agamben.

Ambiguity and Indeterminacy – The Potential and the Possible

It has been argued that accidental likenesses, either in their natural configurations or as aniconic human marks, play a decisive role when figurative or geometric forms first were used as proxies for human images. Concepts such as “ambiguity” and “accidental resemblance” have been used to sustain the thesis around the origin of art (Lorblanchet, 1999, pp. 9–40). Finbarr Barry Flood has shown that since Antiquity through the Middle Ages and beyond, in Modernity, the use of marble as a medium was capable of producing a mimetic effect of the fluid appearance of the walls (Flood, 2016, p. 181). According to him, the “aniconic” images created by marble are “natural images,” that is, images not made by human hands, but “produced by the (direct or indirect) operation of providence itself.” Thus, they are “God’s wonder” (Flood, 2016, p. 210). This aniconic or non-representational image is in fact not an image (or a re-presentation) but pure medium in its immanence, marble as frozen water, nature’s manifestation – a form of God’s creation (Fig. 1a, b).

Potential Images, Fig. 1 (a and b) Interior of the Imperial Church of Hagia Sophia Constantinople (sixth c.) with marble revetments as water simile (private images)

The potentiality of expression of image remains as late as in the Renaissance, when, for example, Alberti in his treatise *De statua* (Alberti, 1972) suggests that the first sculptors had been inspired by noticing in “a tree-trunk, a clump of earth and other similar objects . . . features which, slightly transformed, could be made to resemble completely natural shapes” (Janitschek, 1970, p. 254). The awareness about the creative power generated by accident and imagination is attested in the writings of Leonardo, who perceived artificial production like, for example, the “rough sketch” (*componimento inculto*) as inspirational because “in confused things the mind is aroused to new discoveries” (Leonardo da Vinci, 1956, pp. 35–36). Italian art historian Giambattista Armenini (1587) attempts to elucidate the meaning and presence of the antique grotesques as suggested by “the holes or stains seen in walls that were once completely white” (Morel, 1997, p. 38). Such hypotheses about the origin of art are validated by empirical observations of prehistoric artifacts and cave paintings, notably those by the archaeologist Abbé Breuil at the beginning of the twentieth century and by psychologist G.-H. Luquet in 1926 (Gamboni, 2002, p. 11). The potentiality of image yielded from such accidental imagery latent in nature is the expression of human creativity and human disposition for play.

Imaginative or projective perception has also associated the practice of divination with the early stages of writing in, for example, Mesopotamia and China. This interesting thesis suggests that divination rationalized images and thus made the invention of writing possible. Such a perspective confers images a greater freedom because unlike language, the image needs only an observer to communicate. Ambiguous forms embedded in natural objects stimulate human invention, but new is the idea of the invention of reading as a means of understanding visual messages, as an outcome of rationalizing their messages derived from divination performed by soothsayers (Christin, 1995, p. 103).

The theory and the practice of modern art have been involved in the observation of this phenomenon and made ambiguity a central element of their relationship with the viewer. In his *The*

Creative Act (1957) Marcel Duchamp coined the term “art coefficient” as the “arithmetical relation between the unexpressed but intended and the unintentionally expressed,” followed by his famous dictum: “*Ce sont les REGARDEURS qui font les tableaux*” (“It is the ONLOOKER who makes the pictures”) (Duchamp, 1975, p. 247). From this moment, the notion of “intention” of the artist became problematic in modernity. Duchamp ascribed to the artist solely a “mediumistic role” (Duchamp, 1957, pp. 138–140). The artist is a “mediumistic being” who does not really know what he is doing or why he is doing it. It is the spectator who, through a kind of “inner osmosis,” deciphers and interprets the work’s inner qualifications, relates them to the external world, and thus completes the creative cycle. The field of play, the operation of chance as the expression of such opposition between chance as distraction and lack of sense creates unexpected potentialities that one must take (“take” the chance), a chance that goes beyond the plausible. Duchamp’s nonsense converts the given and the banal into apparitional potency (Sewell, 1952, pp. 55–80, 115–29).

In defining his concept of indeterminacy, Gottfried Boehm is inspired by Wittgenstein’s syntagm “the image has *Spiel*.” He invites us to inquire into the play of image to see how “spaces for free play create unpredicted possibilities,” “the intensification of iconic potentiality” (Boehm, p. 220). He argues that amorphous visual data, as in the painting of Cezanne and other impressionists (Fig. 2), “renew the perception of nature by way of the ambiguity of seeing” (Boehm, p. 221) and allow for “the creation of new plausibilities.” Cezanne calls this process “sensation” or “sensation colorante” (Boehm, p. 222). Sensation, according to Boehm, “opens the door to that potentiality of the image through which the lack of determinacy becomes a surplus of meaning. Its logic is connected to the difference of energies, to the organization of visual forces” (Boehm, p. 222). He claims, “We have identified this energy in the potential that inhabits indeterminacy” (Boehm, p. 228). Boehm defines the *Spiel* of image operating within this play of unpredictable iconic potentialities that create unpredictable possibilities, linking thus the

Potential Images, Fig. 2 Claude Monet, *Rouen Cathedral: Facade (Morning effect)*, 1894, Folkwang Museum Essen, Germany. [https://commons.wikimedia.org/wiki/File:Claude_Monet_-_Rouen_Cathedral,_Facade_\(Morning_effect\).JPG](https://commons.wikimedia.org/wiki/File:Claude_Monet_-_Rouen_Cathedral,_Facade_(Morning_effect).JPG)

possible and the potential. The logic of image is defined as “the iconic difference in which an ‘impossible’ synthesis occurs” (Boehm, p. 228). Taking Husserl’s thought on “shading” one step further, Boehm envisages how “in every perception of ‘something’, an exciting, an ‘impossible’ synthesis of the visible and invisible, of the thematically identifiable and the non-thematic horizon takes place” (Boehm, p. 227). The source of the indeterminate that inhabits the differences of energies is “the locus of imagination” (Boehm, p. 226).

The Life of Forms – Forms of Life. Vital Forces and Potential Images

In his *The Life of Forms in Art* published in 1935, Henri Focillon presents his theory of art, arguing against any art-historical explanation that tries to account for the evolution of artistic form

exclusively from a deterministic point of view. He sums up his view in a referential epigrammatic form: “The most attentive study of the most homogenous milieu, of the most closely woven concatenation of circumstances, will not serve to give us the design of the towers of Laon” (Focillon, *The Life of Forms*, p. 149; Focillon, *Vie des formes*, p. 63) (Fig. 2).

Focillon argues that the study of the work of art will always be insufficient and will not completely serve to account for its entire dimension. The potentiality of the work of art (image) resides in its own form and exceeds the expectation of the viewer, which emerges in the process of its perception. The work of art is for Focillon a singular event, bringing absolute newness into the world. This quality of the work derives from the nature of its artistic form. The metamorphic nature is characteristic of form itself, as opposed to the static notions of image or of sign: “For form is surrounded by a certain aura: although it is our most strict definition of space, it also suggests to us the existence of other forms. It prolongs and diffuses itself throughout our dreams and fancies: we regard it, as it were, as a kind of fissure through which crowds of images aspiring to birth may be introduced into some indefinite realm – a realm which is neither that of physical extent nor that of pure thought” (Focillon, *The Life of Forms*, pp. 34–35; Focillon, *Vie des formes*, 1934, p. 7). The work of art is, as Focillon put it, “the record of an activity that has been in a way set down or incarnated, and which is constantly awaiting reactivation” (Focillon, Introduction by J. Molino, *The Life of the Forms*, p. 20). Indeed, Focillon argues that “form is not only, as it were, incarnated, but that it is invariably incarnation itself” (“[N]on seulement comment la forme est, en quelque sorte, incarnée, mais qu’elle est toujours incarnation”) (Focillon, *The Life of Forms*, 101; Focillon, *Vie des formes*, p. 39). Therefore, form is not a static reality, but “inhabited by a tension, a dynamism that lines it and animates it from within” (Focillon, Introduction, *The Life of Forms*, p. 20). “It [the work of art] lies under our eyes and under our hands as a kind of extrusion upon a world (*une sorte d’irruption dans un monde*)” that has nothing whatsoever in

common with it save the pretext of the image in the so-called ‘arts’ of imitation” (Focillon, *The Life of Forms*, p. 34; Focillon, *Vie des formes*, p. 7).

Here some connections between Focillon and Bergson become apparent, especially as concerns the vitalism the two thinkers share. As suggested in the very title of his book, *The Life of Forms in Art*, Focillon saw artistic forms as living entities, evolving and metamorphosing over time. Focillon’s conception of art forms invested with life owes much to Henri Bergson’s philosophy and his vitalism, as well as to his view of the continuous, living transformation over time, as outlined in Bergson’s first and most important book, *Time and Free Will* (1889). Bergsonian ideas are already reflected in Focillon’s conception of artistic form as an open potentiality rather than as a finished process in his analysis of Hokusai’s art (1914), a breakthrough in art history. By 1935, Focillon published *The Life of Forms in Art*, his philosophy of history of art. In his most popular book, *Creative Evolution* of 1907, Bergson argues that the greatest proof of the possibility of novelty – and, as such, the best counterproof to determinism – came from the artistic realm, an idea that was no doubt appealing to Focillon who felt a special affinity with Bergson’s mode of thinking. Bergson sensed the unforeseeable dimension inherent in the work of art: “The finished portrait is explained by the features of the model, by the nature of the artist, by the colors spread out on the palette, but even with the knowledge of what explains it, no one, not even the artist, could have foreseen exactly what the portrait would be” (Bergson, 1944, p. 9). For “the portrait will surely resemble the model and will surely resemble the artist; but the concrete solution brings with it that unforeseeable nothing which is everything in a work of art” (Bergson, 1944, p. 370). Like Bergson, Focillon grounds his thinking in the living body’s – whether it is the viewer’s or the artist’s – confrontation with the artwork in all its physicality. For the secret of the singular mode of existence that characterizes the work of art, argues the art historian, is that “the art object is distinct from others because of the double relation of production and reception that links it to humanity, artist and

viewer.” “In other words, a work of art is not the outline or the graph of art as an activity; it is art itself. It does not design art; it creates it” (Focillon, Introduction, *The Life of Forms*, p. 20). This creative dimension embedded in the work as a potential force is a continuous expression that differentiates it from other things. And it only exists as such only insofar as all links attaching it to its creator have been severed and made available for a potentiality that emerges within the dialogue of the work with its viewer, beyond any kind of determinism.

Inspired by Bergson, Focillon criticizes both the notion of a homogenized, spatialized notion of time and the notion that context and belief comprise a one-sided causality of the process of artistic creation. He turns to architecture to praise its capacity to create ever new, potentially unforeseeable environments. “It invents a world all its own” (Focillon, *The Life of Forms*, p. 149; Focillon, *Vie des Formes*, p. 63). Like all other artistic creations, architecture is an example of invention and novelty for it acts directly upon society, breaking the determinist logic of development. Discussing the potential infinite number of conditions that could influence the creation of art, Focillon writes: “In those imaginary worlds [of art] in which the artist plays the role of geometer and mechanic, of physicist and chemist, of psychologist and historian at once, form, through the play of its metamorphoses, perpetually goes forward, by its own necessity, toward its freedom” (Focillon, *The Life of Forms*, p. 156; Focillon, *Vie des Formes*, p. 67). He further substantiates this affirmation of freedom over determinism, a direct influence from Bergson, in the realm of art and society.

In Focillon’s theory of art, the notion of style is equally applicable to everything including the art of living. What qualifies style is the material and technique, where technique is not the automatism of the craft, but “a whole poetry of action” (“une poésie toute d’action”), “the means for the achievement of metamorphoses” (“le moyen des metamorphoses”) (Focillon, *The Life of Forms*, pp. 102–103; Focillon, *Vie des formes*, 39–40). Two intimately related aspects of activity are engaged in the technique of the work of art: first,

the trade secrets of a craft, and second, the manner in which these trade secrets bring forms in the realm of matter to life. But as Focillon argues, in examining a work of art we must go beyond mere craft techniques and trace to its source an entire genealogy. This would amount to the reconciliation of passivity with freedom, of “inertia and action” mediated by touch. There is a sense of motion in the “rapidly changing” metamorphosis of forms evolving in this process before the work attains its ultimate form. Focillon employs more than once a musical analogy to describe the “impatient metamorphoses” of form released “under our very eyes, exactly as the pianist’s execution develops a sonata” (Focillon, *The Life of Forms*, p. 105; Focillon, *Vies des forms*, p. 41). The term “impatience” with regard to the technique used by Focillon sounds unclear, but as he argues, nothing could better exhibit this process [than] “the impatience of technique” in respect to its craft: “that technique must extract from matter forces that are still vital and not vitrified beneath a flawless varnish” (Focillon, *The Life of Forms*, p. 106; Focillon, *Vie des forms*, p. 41). To clarify this, Focillon makes again a musical comparison. He argues that the painter sees just as the musician hears, not in musical or pictorial abstractions, but in a sensuous manner. Specifically, the painter sees as the musician hears, not in numeric intervals but in timbers: the painter sees not the abstractions, but the tones, the modeling, and the touch. The touch is the true contact between inertia and action. The touch is an important concept for Focillon, a fluid, phenomenological concept. With the language of touch, the artist composes the language of sight – a “warm” tone, a “cool” tone, a “heavy” tone, a “hollow” tone, a “hard” line, and a “soft” line. “For touch is at the very beginning of Creation.” “Adam was molded of clay, like a statue” (Focillon, *The Life of Forms*, p. 167; Focillon, *Éloge de la main*, p. 9). Rodin’s work “The Creation” (or “The Hand of God”) (Fig. 3), by which the sculptor represents the six days of creation (modeled ca. 1896–1902, carved ca. 1907), which starts up from the block in which the forces of chaos lie dormant, is a formidable metaphor for Focillon (Focillon, *The Life of Forms*, p. 167, Focillon, *Eloge*, p. 9).

Potential Images, Fig. 3 Auguste Rodin, *The Hand of God* or *The Creation*, modeled ca. 1896–1902, carved 1908, The Metropolitan Museum of Art, New York. https://commons.wikimedia.org/wiki/File:RISD_Rodin_Hand_of_God_02.JPG

The hand is the *princeps organon* for the artist: “The hand that is in his mind is at work. It creates the concrete within the abstract, and weight within the imponderable” (Focillon, *The Life of Forms*, p. 123; Focillon, *Vie des forms*, p. 49). Here, in this alchemical transformation, in the imponderable we find perhaps the essence of Focillon’s theory of form, the outermost edge of form expression, its *akmê*. This salient moment in the history of forms, argues Focillon, finds its high point of bloom in Classicism in contrast with academic art. Focillon presents his *akmê* of the form art and LIFE as the pure expression of a potential image:

Classicism: a brief, perfectly balance distant of complete possession of forms; not a slow and monotonous application of ‘rules,’ but a pure, quick delight, like the *akmê* of the Greeks, so delicate that the pointer of the scale scarcely trembles. I look at this scale not to see whether the pointer will presently dip down again, or even come to a moment of absolute rest. I look at it instead to see,

within the miracle of that hesitant immobility, the slight, inappreciable tremor that indicates life. (*Life of Forms*, p. 55, *Vie des forms*, 16)

This is a turning point in the history of artistic forms for Focillon – the peak of life forms, the instant touch of life. This reveals itself as a pure and quick delight experienced in the pointer of the scale. In its delicate tremor, the form performs a sort of “rite of passage” forever hesitant between immobility and trembling. This “critical instant” in space and time is for Focillon a figure of potentiality. Focillon’s *akmê* metaphorically expressed in the imponderable is evocative of the Bergsonian “falling body,” viewed too as an *akmê* and *telos* by the philosopher of *Creative Evolution* (Bergson, 1944, pp. 359–360; Bergson, 1907, p. 193). The falling body with its cinematic disposition of movement seems well captured by the instantaneous photography or by the galloping movement: “a form that appears to radiate over a whole period and so fill up a time of gallop.” “It is this attitude that sculpture has fixed on the frieze of the Parthenon” (Bergson, 1944, p. 361; Bergson, 1907, 194). For both authors, these patterns of form and imagination – Focillon’s tremor of the pointer of the scale and Bergson’s figure of the gallop – are exemplary modes to express the potentiality of image, the suspension of law of physics, and of all determinism. The point of touch between inertia and action, between inspiration and resistance, is the potential. The impact of these specific patterns of thought to carry the potential in Bergson and Focillon’s works is remarkable, especially after the insights of French philosophers of potentiality, most notably Giorgio Agamben, are brought into the discussion.

Agamben’s Form of Life

Giorgio Agamben’s theory of potentiality of artwork thought in relation with his view on work (*opera*) is presented in his book, *Creazione e anarchia. L’opera nell’età della religione capitalista* (Creation and Anarchy: The Work in the Age of Capitalist Religion). Asking the question “what is the work (*opera*)?” Agamben goes back to the opposition between potentiality and

actuality presented in Aristotle’s *Metaphysics*. Unlike Aristotle, Agamben provocatively puts forth the idea that potentiality is not just what is actualized, embodied in the work, but also what could not be actualized. *Adynamia* is not a mere lack of potency, but the potency-of-not-being turned into actuality of the work. For Agamben, every human potential is constitutively impotential: “[T]he human is the living being that exists eminently in the dimension of potential, of being-able-to and being-able-not-to” (Agamben, 2019, p. 20). Therefore, the act of creation – *poiesis* as production – resists the full accomplishment of converting potency (*dynamis*) into act (*energeia*). Giving a new meaning to the potency-of-not in a work of art, Agamben projects a new view on potency, which is something not fully exhausted in the accomplished act of creation. Thus, the work is the outcome of a dialectic between the potency-of, conceived as the impersonal element or “inspiration,” and the potency-of-not, the personal element that resists actualization. Potential is an ambiguous being that not only is capable both of something and of its opposite, but also contains in itself an intimate and irreducible resistance. The act of creation is “a field of forces stretched between potential and impotential, being-able-to and being-able-not-to, acting and resisting” (Agamben, 2019, p. 20). To untangle this field of apparently contradictory forces engaged in the act of creation, Agamben turns to Focillon’s *akmê* associated with the classical form and presented already above. Walter Benjamin quotes this very same passage in his notes on the character of the dialectical image – the vision of the delicate tremor of the pointer of the scale, hesitant between immobility and trembling:

What is at stake is, rather, that ‘light, imperceptible trembling’ in the very immobility of the form, which, according to Focillon, is the insignia of classical style. (Agamben, 2019, p. 21)

Focillon’s pattern of the trembling pointer of the scale finds a remarkable echo in Agamben’s further elaboration on the potential: he offers an alternative vision coming from Dante’s poetics, namely, the trembling hand of the artist. This Dantesque line is the nexus of Agamben’s theory of inoperativity: *l’artista / ch’a l’abito de l’arte ha man che trema*

(the artist who has the habit of art has a hand that trembles; *Paradiso* 13.77–78) or, according to another reading, *ch' ha l'abito de l'arte e man che trema* (who has the habit of art and a hand that trembles; Agamben, 2019, p. 21). The trembling gesture is not a failure of the artist's hand, but a virtue, just as the trembling pointer is for Focillon the *akmé* of form. As Agamben clarifies, there is no contradiction between habit and hand in the act of creation, but this is the perfect expression of the twofold structure of every authentic creative process, suspended between two contradictory urges: thrust and resistance, inspiration and critique. This principle pervades the entire poetic act, for habit already contradicts inspiration, which comes from elsewhere and cannot be mastered by habit. In this sense, the resistance of the potential-not-to, by deactivating the habit, remains faithful to inspiration and almost prevents it from reifying itself in the work: the inspired artist is without work (Agamben, 2019, p. 22).

Agamben goes on making Dante's poetic line a principle in his interpretation of the act of creation and provides a new fresh reading of Titian's *Annunciation* (Fig. 4), elaborating on the trembling hand of the artist, a trembling that is not a deficiency, "but this trembling is supreme mastery" (Agamben, 2019, p. 23).

Titian's magnificent canvas, housed in Venice's San Salvador church, arrests the viewer's

Potential Images, Fig. 4 Tizian (Tiziano Vecellio), *The Annunciation*, 1559–1564, Church of San Salvador, Venice. <https://gallerix.org/pic/T/889526648/5247.jpeg>

eyes especially with its "crackling magma" where "flesh trembles" even [in] the wings of the angels, where "lights fight the shadows" (Agamben, 2019, p. 22). The painter's unusual signature seems to betray something of the wrestling hand with the painterly lava: *Titianus fecit fecit* ("made it and remade it"), that is, almost unmade it (Agamben, 2019, p. 23). Another line on the bottom of the painting below the flower pot reads: *ignis ardens non comburens*, which iconographically refers to the Biblical bush from Exodus (Ex. 3:2–4), which burns without ever being consumed, a metaphor for the Virgin's purity. Agamben's point is that this Latinized quote of the Biblical saying might have been inserted by Titian precisely to stress "the specific character of the act of creation, which burned on the surface of the canvas without, however, being consumed – a perfect metaphor for a potential that is in flames without exhausting itself" (Agamben, 2019, p. 23). It is why the artist's hand trembles, argues Agamben, "his trembling is his supreme mastery." "What trembles and almost dances in the form is potential: *ignis ardens non comburens*" (Agamben, 2019, p. 23). For, as Agamben put it,

mastery is not formal perfection but quite the opposite: it is the preservation of potential in the act, the salvation of the imperfection in the perfect form. In the painting of a master or on a page from a great writer, the resistance of the potential-not-to is marked in the work as the intimate mannerism present in every masterpiece. (Agamben, 2019, p. 21)

It is this indefinable holding-back amidst the plenitude of the work, the kind of restraint, and tact, that Agamben calls "inoperativity." "In a word – and this is, at least in art, the decisive element – its *grace*" (Agamben, 2019, p. 28).

More than 30 years later, El Greco depicted the same event of the *Annunciation* (Fig. 5) with enflamed bush. The vibrant quality of the painting surface and the energetic use of *colore* create a vision similar to the unconsumed mystery of Titian that Agamben saw as the unexhausted figure of potentiality. The singular, inscrutable character of El Greco that unites "the transcendental" with "the immediate" derives from the fusion between two impossible moments, the Byzantine

Potential Images, Fig. 5 El Greco (Doménikos Theotokópoulos) – *The Annunciation*, ca. 1596–1600, Bilbao Fine Arts Museum, Bilbao, Spain. https://upload.wikimedia.org/wikipedia/commons/7/71/El_Greco_-_28Dom%C3%A9nikos_Theotok%C3%B3poulos%29_-_The_Annunciation_-_Google_Art_Project_%28807333%29.jpg

transcendentalism and the Renaissance illusionism, an intriguing parallelism that could not reduce El Greco's work to a simple reflection of Spanish mysticism (Yasunari Kitaura, 2003, p. 64). This might explain El Greco's note in the margins of his personal copy of Vitruvius's *Ten Books on Architecture*: "Painting deals with the impossible" (*La pintura trata de lo imposible por lo mismo imperfecta*). El Greco's impossible work appears to be a symptom of preservation of potentiality in the act, "the salvation of the imperfection in the perfect form."

Conclusion

"Potential images," and the related concept "potentiality," have been theorized within the

field of art history and the theory of image, as well as in philosophy. Specific patterns of vision, such as ambiguity, indeterminacy, immersion, hidden images, and the barely perceptible trembling of the artist's hand, create new potentialities for image, stimulating the spectator's imaginative response through the participation of the onlooker. Such an aesthetic experience depends upon an active collaboration between artist, artwork, and onlooker, adding ever new potentialities to image perception. This entry has presented some important aspects of potentiality from a historical perspective and discussed some modes of the operation of potentiality of image, especially to demonstrate the fruitfulness of accidental images and imaginative perception for the invention of the pictorial subject and to point out to a specific dimension of artistic creativity that reveals the playful side of the phenomenon. The anti-determinist positions outlined by various theoretical stands reject art-historical explanations that try to account for the evolution of artistic form through exclusively contextual factors and that deny any possibility of free will and human freedom reflected in human creativity as a source of potentiality of image beyond determination. Agamben's view of the potential with reference to the work of art inscribes itself in a long position in Western philosophy and stands out as well as an act of resistance, where to resist always means to free a potential of life. It is a potentiality that "does not precede the work, but accompanies it and makes it live ... The life that contemplates its own potentiality to act and not to act becomes inoperative in all its operations, lives only its livableness." The trembling hand is supreme mastery for "mastery is not formal perfection but quite the opposite." It is an enduring poetic metaphor of *mannerist* potentiality. For Agamben, life is preserved in and as form: what he calls form-of-life.

Pragmatism

Guilherme Sanches de Oliveira

Department of Biological Psychology and Neuroergonomics, Technische Universität Berlin, Berlin, Germany

Abstract

Pragmatism is a school of thought popularized in the beginning of the twentieth century by American psychologist and philosopher William James. Although most widely known (and criticized) for its theory of truth, pragmatism is a far broader position, connecting to issues in psychology, education, ethics, religion, and politics. This entry gives an overview of pragmatism particularly as developed by James. It begins by describing pragmatism's historical development and presenting the pragmatist contribution to philosophical debates about truth. From this, the entry moves to discussing pragmatism's broader significance, and it does so by highlighting how pragmatism's emphasis on practical effects relates to cognitive and existential possibilities: Our habits both limit and enable the range of behaviors available to us, but they can also be worked on so as to bring us closer to better possibilities, including possibilities for our own personal development and for making life more meaningful, as well as possibilities for how we approach life in society.

Keywords

American pragmatism · William James · Practical effects · Truth · Development · Habit · Cognition · Meaning · Pluralism

Introduction

In a broad colloquial sense, the term "pragmatism" suggests an attitude of approaching problems without getting bogged down into abstract considerations and "idealistic" expectations: The pragmatic person has a down-to-earth, "realistic"

outlook and does what they can with what they have, knowing that, as the famous aphorism goes, perfect is the enemy of good. This ordinary connotation of “pragmatism” is certainly related to the technical meaning of the term in academic circles, but it is also relevantly different – as much as the “realism” and “idealism” mentioned above differ from their philosophical counterparts. As a school of thought, pragmatism is often described as the quintessential American philosophy, an approach that broke away from both the mainland European and the British traditions to forge a whole new way of addressing philosophical problems, solving some of them, and dissolving others. This entry presents some key themes in pragmatism, beginning with an overview of the pragmatist theory of truth and meaning, and then proceeding to articulating broadly construed “cognitive” and “existential” dimensions of pragmatist thought. Throughout, the entry will emphasize how pragmatist ideas relate to possibility, and, in light of this connection, it will conclude by clarifying how pragmatist philosophy differs from, and can enrich, “pragmatic” thinking in the colloquial sense just described. But, first, a brief historical sketch is in order.

Historical Background

Pragmatism was popularized by William James (1842–1910) in a collection of lectures published as a book in 1907 under the title *Pragmatism, a New Name for Some Old Ways of Thinking*. James credited his friend Charles Sanders Peirce (1839–1914), and in particular Peirce’s 1878 article “How to make our ideas clear,” with having set up the conceptual foundations for pragmatism. Curiously, Peirce would dispute this claim, distancing himself from James’ formulation and calling his own view “pragmaticism” instead (see Peirce 1905). The other canonical figure widely recognized as one of the so-called Classical American Pragmatists is John Dewey (1859–1952), whose 1903 book *Studies in Logical Theory* James cites alongside other articles (Dewey 1906a, b, c, 1907) as contributions to pragmatist thought (see also

► [The Possible in the Life and Work of John Dewey](#)). Besides Peirce and Dewey, James acknowledges Oxford philosopher F. C. S. Schiller (1864–1937; Schiller 1907) as well as members of the “Chicago School” led by Dewey, such as George Herbert Mead (1863–1931; Mead 1903; see also ► [George Herbert Mead](#)), as developing views relevantly similar to his own (James 1904, 1907). Other scholars contemporaneous with James who were linked to pragmatism outside of philosophy included American jurist and associate justice of the United States Supreme Court, Oliver Wendell Holmes Jr. (1872–1929; see Menand 2001), and sociologist and civil rights activist W. E. B Du Bois (1868–1963; see Taylor 2004). Later philosophers influenced to varying degrees by the classical pragmatists include analytic pragmatists and neopragmatists such as C. I. Lewis (1883–1964), Willard van Orman Quine (1908–2000), Hilary Putnam (1926–2016), and Richard Rorty (1931–2007), as well as contemporary philosophers of very diverse orientations such as Robert Brandom, Susan Haack, Cornel West, and Jürgen Habermas, to mention just a few (see Legg and Hookway 2021).

Pragmatism enjoyed great popularity in the period immediately following James’ lectures, in large part due to the amount of criticism its theory of truth attracted (more on this in the next section). This initial notoriety led to relative obscurity, up until pragmatism was rediscovered in mainstream academic philosophy in the past few decades. This history is well documented. Menand’s Pulitzer Prize award-winning 2001 book *The Metaphysical Club: A Story of Ideas in America* offers an engaging account of the historical political, cultural, and intellectual environment in which pragmatism emerged. Different aspects of pragmatism’s later historical development appear in discussions by Schwartz (2012) and Misak (2016), while Shook and Margolis (2006) and Stuhr (2009) each offer rich collections of essays commemorating the centenary of James’ book. Reflecting the more recently renewed interest in pragmatism, a number of general introductions have begun to crop up, including many excellent ones (see Wilshire 2000; Talisse and Aikin 2008; Bacon 2012; Spencer 2020), as well as

anthologies with primary sources from the classic to the contemporary (Menand 1997; Talisse and Aikin 2011). A topic of growing interest is pragmatism's relation to ideas outside philosophy, especially in the natural sciences: On this, see Trevor Pearce's (2020) *Pragmatism's Evolution: Organism and Environment in American Philosophy*, which traces pragmatism's biological roots (and branch and flower and fruit); another recent contribution worth mentioning is Crippen and Schulkin's (2020) *Mind Ecologies: Body, Brain, and World*, which emphasizes the contemporary relevance of pragmatism for the sciences of the mind, and in particular the pragmatist influence on embodied approaches in cognitive science.

Pragmatism, Truth, and Meaning

Since its inception, pragmatism has often been doubly misunderstood in mainstream academic philosophy, on the one hand, as being a theory of truth and not much else, and, on the other hand, as a bad theory at that. This is a mistake. From the start, pragmatism had much more to offer than simply a view on the nature of truth; moreover, what it did have to say about truth was wildly misinterpreted by critics.

In the common misinterpretation, the pragmatist theory of truth is seen as a competitor to the correspondence theory of truth, both of which, in turn, are attempts to answer the question *what is "truth"?* The intuitive answer is that an idea, statement, or belief is true to the extent that it agrees with reality: Truth, in this sense, is usually defined as accurate representation of, or correspondence to, the way the world actually is. In contrast, James famously proposed a view that equated an idea's truth to its expediency or instrumental usefulness:

Any idea upon which we can ride, so to speak; any idea that will carry us prosperously from any one part of our experience to any other part, linking things satisfactorily, working securely, simplifying, saving labor; is true for just so much, true in so far forth, true instrumentally. (James 1907, p. 58)

This pragmatist position is often misconstrued as proposing that *truth is whatever works*, that is, an

idea, statement, or belief is true to the extent that it leads to good consequences – so that it is acceptable to believe falsehoods when the belief is beneficial to the believer and, moreover, that in such cases the falsehood is even to be counted as true! This way of framing the pragmatist view of truth was ridiculed (and rightly so) by many then and ever since, prominently including Bertrand Russell (see Russell's 1908 paper republished under the title "William James's Conception of Truth" in Russell 1910; also Russell 1945; and discussion in, e.g., Putnam 1992). Already in the 1907 book James acknowledges and rejects a version of this misinterpretation and criticism, stating: "Dewey says truth is what gives 'satisfaction.' He is treated as one who believes in calling everything true which, if it were true, would be pleasant" (James 1907, p. 234). The continued popularity of misconceptions like this one led James to publish, 2 years after the first *Pragmatism* book, a follow up titled "*The Meaning of Truth: A Sequel to 'Pragmatism'*" (James 1909). Thankfully, this supposedly pragmatist view is a caricature, and not at all what James and others proposed.

The pragmatist view of truth as put forward by James was not meant to be an alternative to the view that truth is a matter of agreement with reality: Rather, as James explicitly put it, the concern is with clarifying "what may precisely be meant by the term 'agreement,' and what by the term 'reality,' when reality is taken as something for our ideas to agree with" (James 1907, p. 198). And agreement with reality, James proposed, is a very practical matter. In what would become one of the most famous statements of this view James claims: "'The true,' to put it very briefly, is only the expedient in the way of our thinking, just as 'the right' is only the expedient in the way of our behaving" (James 1907, p. 222). Were this the whole story, the critics might have a point. But James further clarifies that, in equating an idea's truth to its expediency, he has in mind a process that unfolds over time rather than merely a static property an idea might have of being instrumentally useful in the here and now. The passage continues with James explaining that he means "expedient in the long run and on the whole of course; for what meets expediently all the

experience in sight won't necessarily meet all farther experiences equally satisfactorily" (ibid.). Over the long run, an idea that at first served as a good guide for action may turn out to be less adequate than expected for dealing with novel problems and situations. When this happens, and we act on an idea but the world pushes back, we discover reasons to revise our way of thinking. This does not mean that the idea was entirely wrong, but just that it is no longer right enough given the novel circumstances.

There are two important aspects to the move James is making here. The first is this. If we see "truth" according to the correspondence view, as a matter of accurately copying or representing reality, then it follows that an idea may be true and at the same time be useless, or that it may be useful but false. This takes for granted a distinction between the true and the good, a distinction that seemed inadequate for James. As he puts it, "truth is one species of good, and not, as is usually supposed, a category distinct from good, and coordinate with it. The true is the name of whatever proves itself to be good in the way of belief, and good, too, for definite, assignable reasons" (James 1907, pp. 75–76). Later on, he elaborates on this idea:

To copy a reality is, indeed, one very important way of agreeing with it, but it is far from being essential. The essential thing is the process of being guided. Any idea that helps us to deal, whether practically or intellectually, with either the reality or its belongings, that doesn't entangle our progress in frustrations, that fits, in fact, and adapts our life to the reality's whole setting, will agree sufficiently to meet the requirement. It will hold true of that reality. (James 1907, p. 213)

In the case mentioned above, of an idea that later turns out to be less useful than it had been at first, we do not have to conclude that it was false: If at first it worked to some extent, that is reason to think that it was true, at least partially; and this is precisely the intuition that pragmatism attempts to ground philosophically by equating truth to expediency – expediency admits of degrees and can be context-specific.

Besides this rejection of the assumption that truth and goodness are distinct and independent characteristics of ideas, a second aspect of the

pragmatist view is worth emphasizing. This is the proposal, already alluded to, that truth is a process rather than a static property. As James puts it, "True ideas are those that we can assimilate, validate, corroborate and verify. False ideas are those that we can not" (James 1907, p. 201), to which he adds:

The truth of an idea is not a stagnant property inherent in it. Truth happens to an idea. It becomes true, is made true by events. Its verity is in fact an event, a process: the process namely of its verifying itself, its verification. Its validity is the process of its validation. (James 1907, p. 201)

As already seen, when James equates truth to expediency, he emphasizes the importance of thinking of expediency in the long run. Now framing truth as a process, we see that it is over time, as our ideas get applied and tested, that they can turn out to be worth believing and acting on. An idea that gets verified and validated is an idea that agrees with reality to the relevant extent and is thereby an idea that gets made true. It is in this sense that James proposed, "Truth for us is simply a collective name for verification-processes," further adding, "Truth is made, just as health, wealth and strength are made, in the course of experience" (James 1907, p. 218). In contrast with thinking, for instance, that an organism is healthy because it contains within itself a distinct positive property of "health," it makes sense to see the label as more simply denoting the organism's having so far withstood the test of experience (e.g., exposure to pathogens and potential accidents without grave consequences). Similarly, James proposes, an idea is not true because it has a static property (e.g., the property of accurately representing reality) but, rather, it is made true – and more or less so – over time, through the test of practical experience.

The pragmatist theory of truth, then, is not meant as an alternative to the view that ideas are true to the extent that they agree with reality: Rather, it is a clarification of this view. An idea agrees with reality when we act on the idea, or act guided by it, and over time the idea proves to work in relevant ways, successfully connecting current experiences with previous ones, and adequately preparing us to move forward and face new

possibilities in the novel experiences to come. And, importantly, none of this was supposed to be novel and revolutionary. In the subtitle of his 1907 book, James described pragmatism as “A New Name For Some Old Ways Of Thinking.” This is, as already noted, partly a nod to Peirce. For Peirce, we attain the greatest clarity in our thinking about some object when we can identify how our thinking relates to practical effects. When it comes to abstract concepts or theoretical constructs in science, for instance, there is only so much we can advance in our understanding by distinguishing these from other concepts and constructs: The clearest understanding of the object in question comes when we can operationalize it in terms of measurable interventions and manipulations along with their practical effects. In this sense, James is elaborating on, and giving a new name to, this older method proposed by Peirce of identifying an idea’s meaning by tracing that idea’s practical effects. But besides recognizing Peirce’s contribution, James’ description of pragmatism as “a new name for some old ways of thinking” can also be seen as a nod to common sense. In emphasizing, on the one hand, that truth is a kind of good (rather than a distinct property independent from expediency) and, on the other, that truth is a process (i.e., of verification), James offers a way of cashing out the philosophical conception of truth in terms that apply to everyday life and that ordinary folk will recognize, even if some philosophers will find dubious: Truth is made when and where the rubber meets the road. Truth *is* agreement with reality, but it is an agreement that is earned through practical tests and over time: In this sense, truth is the name for our ideas’ expediency rather than an independent characteristic that can make ideas useful; in other words, truth is itself a practical good, rather than a source of good and instrumental success.

Pragmatism and Cognitive and Existential Possibility

The importance of experience and practical effects in pragmatist thought goes far beyond these more widely known but narrower

applications in philosophical discussions about truth and meaning, extending also into domains as varied as education, ethics, religion, and politics. And underlying all of these, especially for James, is pragmatism’s psychological dimension.

Although James’ contributions to the development of psychological science precede, by decades, his publications on pragmatism, already in these earlier writings pragmatism is present in spirit even if not yet in name. James’ *Principles of Psychology*, for instance, was published in 1890 but contained material from at least as early as 1878, and it can be read as putting forward a picture of psychological science and mental phenomena that was pragmatist through and through. One dimension of this pragmatist orientation is made evident by the specific way in which James saw psychology as continuous with biological science. In contemporary usage, “biological psychology” tends to have a reductionist flavor, denoting explanations of mind and behavior in terms of physiological mechanisms, especially at the genetic and neural levels (see popular textbooks, e.g., Toates 2007; Garrett 2009; Barnes 2013; Kalat 2015). This strategy of explaining behavior by reference to elementary intra-organismic causes was already popular in James’ time, especially among those developing psychophysical and structuralist approaches (e.g., Wundt and Titchener). In contrast, James’ approach was to understand mind in terms of the relations that organisms bear to their environment: For James, we can only make sense of mental phenomena by understanding their practical conditions and effects, or the life context in which they are situated in the first place (see Heidbreder 1933; Leary 2018). This might seem like a move away from biological explanation, but it was in fact a perspective that James inherited from the distinctly naturalist and ecological orientation in biology developed by Darwin. For Darwin, the diversity of species could not be accounted for solely by intraorganismic processes (e.g., mutations) without reference to interactions among organisms and between organisms and their surroundings, in their real contexts, as they unfold and change over (evolutionary) time. James applies the same explanatory strategy in the domain of psychology.

For him, mind cannot be equated to internal processes nor to inward-looking abilities for abstract reasoning and detached reflection: Rather, he proposes, the defining characteristic of mind is the situated and practical “pursuance of future ends and the choice of means for their attainment” (James 1890, p. 21). Psychological science, then, is founded on a “biological conception” that is also equal parts pragmatist: “man, whatever else he may be, is primarily a practical being, whose mind is given him to aid in adapting him to this world’s life” (James 1899, p. 25).

Besides inspiring a whole new way of doing research in the sciences of the mind (Heft 2001, Crippen and Schulkin 2020; see also ► [Extended Mind](#)), this radically situated, pragmatist biological conception of our mental lives has far-reaching implications for several domains. In his *Talks to Teachers on Psychology* James emphasizes its educational significance, claiming: “Education, in short, cannot be better described than by calling it the organization of acquired habits of conduct and tendencies to behavior” (James 1899, p. 29). Instruction and learning, whether formal or informal, do not amount to the transmission of “knowledge” understood as the memorization of abstract bits of information. And even reframing knowledge as being about embodied habits, although a move in the right direction, can still fall short from what James is proposing. The metaphor of knowledge as something that can be transmitted at all suggests the possibility of an absence of knowledge: That is the learner’s state prior to the transmission. But this does not work for thinking about habits because the absence of habits is impossible. Living creatures, James explains, are “bundles of habits” (James 1890, p. 109): We are bundles of patterned possibilities for behavior or conduct that we have developed due to our plasticity, that is, due to “the possession of a structure weak enough to yield to an influence, but strong enough not to yield all at once” (p. 110). All of us already have all kinds of habits because of how we have been shaped by experience: “We learn all our possibilities by the way of experience” (p. 1099). And that is why the goal of education is not

the *acquisition* of habits, as if we did not have any in the first place, but rather the *organization* of the habits that already make us who we are: Education of one sort or another is the steering or constraining of those habits in this or that direction, toward some practical possibility aimed for. Based on this fundamental principle, James offers a number of recommendations to instructors that resonate with more recent pedagogical trends emphasizing cooperative, active learning. And he also makes recommendations to learners, for instance, warning students against trying to prepare for exams by cramming (James 1890, pp. 623–624). Importantly, these implications of a pragmatist, biological view of our mental lives apply to all development, not only that which happens in formal schooling. As James puts it, “The great thing, then, in all education, is to make our nervous system our ally instead of our enemy,” to which he adds, “For this we must make automatic and habitual, as early as possible, as many useful actions as we can, and guard against the growing into ways that are likely to be disadvantageous to us, as we should guard against the plague” (James 1890, p. 126).

This pragmatist, biological emphasis on habit, or the plasticity of our practical possibilities, also has important moral, spiritual, and political implications. James illustrates this in his essay titled “Is life worth living?” (James 1895). There, he rejects the usual perspectives that go for absolute answers. Instead of categorically affirming the positive worth of all of life or pessimistically denying it, James emphasizes the open-endedness of our existence. His answer is *maybe*: Life may not be worth living, but it can be; ultimately, this depends on the liver, because life “is what we make it” (James 1895, p. 22). Some people living in quite adverse circumstances come to contemplate the possibility of suicide, as James himself did, and he concedes that it could well be that their existence is not worth continuing. But that is not something you could be certain of. For the religiously inclined, faith can be a reasonable and rationally justifiable source of significance (on this, see James’ 1896 essay *The Will to Believe* and his 1902 book *Varieties of Religious*

Experience; see also ► [Spirituality](#)). For others, “mere instinctive curiosity, pugnacity, and honor may make life on a purely naturalistic basis seem worth living from day to day” (1895, p. 15). Most basically, even though there may be many aspects of life we cannot control, what anyone *can* do something about is their attitude and outlook, the way they habitually approach and deal with life’s circumstances. We can, for instance, “conquer undesirable emotional tendencies in ourselves” if only we persevere in “[going] through the outward motions of those contrary dispositions we prefer to cultivate”: Accordingly, James advises, “Smooth the brow, brighten the eye, contract the dorsal rather than the ventral aspect of the frame, and speak in a major key,” and sooner or later “The reward of persistency will infallibly come, in the fading out of the sullenness or depression, and the advent of real cheerfulness and kindness in their stead” (James 1884, p. 198; see also ► [Emotion](#)). There is no guarantee that this will be enough of a consolation in our darkest hour, but it just might work. In the face of uncertainty, the pragmatist stance is that life can be meaningful if we make it so: “possibilities, not finished facts, are the realities that we encounter” (James 1895, p. 23), so “Believe that life *is* worth living, and your belief will help create the fact” (p. 24). As an answer to the question whether life is worth living, this may not seem as satisfying as categorical affirmative or negative answers, James concedes, but it is an honest answer.

Life’s radical open-endedness is thus both constrained and enabled by our habits. The plasticity we exhibit in our ways of encountering life’s circumstances makes it possible for us to develop and learn in certain directions (that is education in the broad sense), and it also empowers us to construct meaning and significance in the pursuit of new practical possibilities. And these considerations at the individual level also bear an important lesson for life together, in society.

We are plastic bundles of habit, which means that our experiences shape us over time in part through the influence from the environment and in part through our resistance to that influence. This transactional process of development opens up

new cognitive possibilities but also closes off others. And this is so not only in the usual contemporary sense of “cognitive” as synonymous with “psychological”: In this sense, dominant since the Cognitive Revolution of the 1950s and 1960s (Miller 2003; Boden 2008), it follows from the picture provided by James that development (i.e., the organizing of certain habits) leads to cognitive specialization in that it gives us mental abilities we did not previously have, but in so doing it also precludes others; our coming to be *this* bundle of habits means that we have not become *that* other bundle of habits. But there is more to it. The term “cognitive” derives from the Latin *cognoscere* (meaning “to know”), and, traditionally, it included an epistemic dimension. This richer sense was the usual one in James’ time, and according to it a cognitive process is not simply a process that goes on inside the mind, but it is a process of coming to know something: In this sense, psychological phenomena such as perception, memory, or language are cognitive to the extent that they play an epistemic role, contributing to our achieving knowledge of the world. And in this sense, development opens up possibilities for knowing and understanding aspects of reality while also limiting other ways of knowledge and/or limiting our knowledge of reality to some aspects rather than others.

As practical beings, James explains, each of us “is bound to feel intensely the importance of his own duties and the significance of the situations that call these forth” (1899, p. 229–230). Our particular embodied, situated existence makes certain aspects of the world more salient, and some possibilities more compelling or repulsive, than others. This unavoidably unique perspective we have on the world has as its counterpart “a certain blindness,” as James puts it, namely “the blindness with which we all are afflicted in regard to the feelings of creatures and people different from ourselves” (1899, p. 229). For James, coming to understand this fundamental character of our embodied cognitive (i.e., psychological but also epistemic) existence motivates adopting a pluralist attitude and embracing a politics of tolerance. We may be unable to understand why others act in certain ways, but we can appreciate

the fact that, like us, they are approaching the world from a unique point of view from which those actions appear as compelling, valuable, and perhaps even necessary. For James, “the truth is too great for any one actual mind (...) to know the whole of it” and “The facts and worths of life need many cognizers to take them in. There is no point of view absolutely public and universal” (James 1899, p. v). And so, beyond simply informing how we think about education or the meaning of our own life as individuals, the pragmatist picture inspires seeing others as similarly embodied bundles of habits who have developed in particular ways that might have endowed them with cognitive and existential possibilities we just cannot know or understand very well. Pragmatist thought and its emphasis on practical effects, then, has a very clear practical consequence: “The practical consequence of such a philosophy is the well-known democratic respect for the sacredness of individuality” and “the outward tolerance of whatever is not itself intolerant” (James 1899, p. v).

Conclusion

As seen at the beginning of this entry, “pragmatism” in a colloquial sense suggests a down-to-earth and perhaps even narrow-minded attitude of favoring what is most feasible over other potentially better but less practical possibilities. The previous sections showed that pragmatism in the philosophical sense *is* indeed concerned with emphasizing practical effects in many different domains. Importantly, however, the emphasis that pragmatism (in the narrow, technical sense) places on the practical is intimately connected to its emphasis on exploration of, and openness to, the wide range of possibilities available to us. In a personal letter he wrote in 1906, James makes the following observation:

I have no doubt whatever that most people live, whether physically, intellectually or morally, in a very restricted circle of their potential being. They make use of a very small portion of their possible consciousness, and of their soul’s resources in

general, much like a man who, out of his whole bodily organism, should get into a habit of using and moving only his little finger. (James 1906/1920, pp. 253–254)

The specific context of this claim is interesting. James’ correspondent, W. Lutoslawski, had tried to convince James (then in his mid-sixties) to take up yoga, to which James responded in this letter that he had tried some breathing exercises but had found them unpleasant and unhelpful. In the passage immediately preceding the quote above, James notes that, based on Lutoslawski’s description of its effects, yoga might just be “a methodical way of waking up deeper levels of will power than are habitually used, and thereby increasing the individual’s vital tone and energy” (James 1906/1920, p. 253).

We often fail to notice or act on the full range of possibilities available to us. James’ observation makes sense in light of his pragmatist description of humans as bundles of habits and practical beings who are both empowered and limited by their plasticity. But pragmatism also motivates working to expand our boundaries and explore the unknown. And this is something that the specific context of James’ observation – namely his experimenting with bodily practices and disciplines – makes quite vivid. More than a theory of truth, pragmatism encompasses a view of the nature of education, the significance of life, and democratic coexistence, and underlying all of these, a view of what it means to be human. In these different domains, pragmatism emphasizes practical effects, but it does so to encourage openness to new possibilities rather than the narrow-minded closing off to them in favor of whatever seems most practical and convenient. This is in line with James’ description of pragmatism as being ultimately simply a *method* or “an attitude of orientation”: “The attitude of looking away from first things, principles, ‘categories,’ supposed necessities; and of looking towards last things, fruits, consequences, facts” (James 1907, pp. 54–55). This attitude helps us tackle deep metaphysical and epistemological problems, for instance, pushing forward our

understanding of the nature of truth and meaning. But it is very practical as well. Pragmatism invites us to think differently about life in its most mundane aspects and to enrich it by exploring new possibilities for ourselves and for society: It just might work out.

Prisons

Carolina De La Torre Ugarte
Independent Scholar/Consultant, Geneva,
Switzerland

Abstract

A prison is a securitized building housing for convicted persons for long amounts of time with permission by law to punish individuals inside for their crimes and to deter others from offending. Though practices of incarceration and confinement can be traced back to ancient times, the historical antecedents of the modern-day prison began less than 400 years ago in the seventeenth century. Aside from common facilities in most prisons such as sleeping quarters, cooking/eating areas, health services, and recreational spaces, prisons are defined by their lawful deprivation of individuals' liberty and their obligation to provide basic care. Adherence to the minimum standards of custody and care, outlined in the Mandela Rules, is not always achieved and failure to do so often escapes national or international reproach. This is due in part to perceptions of prison as an embodied state of exception in which a certain level of disregard for rights is socially acceptable. Though people in detention are labeled as dangerous, the majority of the prison population is incarcerated for nonviolent offenses stemming from addiction, poverty, and other social problems. From the standpoint of Appadurai's conceptualization of the possible as a hopeful endeavor toward a more equitable society, reflections on prison and the possible explore reforms, alternative sanctions, and the abolitionist question of how else can society carry out justice without a prison.

Keywords

Prison · Detention · Incarceration · Penal reform · Criminal justice reform · Prison abolition

Introduction

A prison is a securitized building housing for convicted persons for long amounts of time with permission by law to punish individuals inside for their crimes and to deter others from offending. For sociologist Erving Goffman, prisons fall into the category of what he dubbed a *total institution*: “A total institution may be defined as a place of residence and work where a large number of like-situated individuals, cut off from the wider society for an appreciable period of time, together lead an enclosed, formally administered round of life” (Goffman 1961, p. xiii). Due the regimented nature of prison life by prison management, he goes on to add that individuals residing within total institutions “all their essential needs will have to be planned for” (Goffman 1961, p. 10). Though total institutions include other closed facilities such as nursing homes or mental health institutions, the term provides a point of departure for the defining characteristics of a prison. Other forms of detention sometimes coterminous with prisons include immigration detention, juvenile detention, security detention, administrative detention, and military detention.

The etymology of the word prison derives from the Latin *prehendere* “to take,” in line with the concept of apprehending someone and taking them into one's custody or under their care. It should be noted that in English, prison and jail are separate buildings in which the former is reserved for convicted individuals, or are found guilty of a crime, and a jail houses individuals waiting for trial. Outside of the English-speaking world, prison can refer to both prison and jail (like in France).

History

Though practices of incarceration and confinement can be traced back to ancient times, activities

such as taking prisoners of war, jailing debtors, or indenturing servants were not reflective of the present-day form of a modern prison. According to historical and penal scholars, the historical antecedents of the modern-day prison are estimated to have begun in the seventeenth century. Before the modern-day prison, punishment for crimes took a more immediate form. People were locked in jails for short periods of time either to pay back debts or to await trial. If found guilty, the sentence usually resulted in some form of public corporal punishment or, in more serious cases, very painful death. Philosopher and historian Michel Foucault famously opens his book *Discipline and Punish* with an account of the grueling drawing and quartering of Robert-François Damiens in 1757 for the crime of attempted regicide of King Louis XV (Foucault 1975). This account is notable for two reasons. First, it illustrates the violence and horror of punishment methods of the time. Second, as the final recorded account of drawing and quartering in France, it harkens the end of punishment as public spectacle and the beginning of *The Birth of the Prison*, the subtitle of Foucault's book.

It was during the French revolution and the penning of concepts like rights in the Declaration of the Rights of Man and of the Citizen where voices of dissent began to emerge, denouncing the depravity and inhumanity of punishment as public spectacle. With growing dissemination of the ideas of human rights, the object of punishment shifted from the body to the soul. Prisons started being used to lock bodies away for longer amounts of time, sparing their lives and limbs in exchange for discipline and penitence (origins of the term penitentiary). Discipline was achieved through regimented schedules and hard labor, training individuals to follow lifestyles in line with societal norms and values. Foucault argued that discipline and punishment of the body and soul grew into a major form of social control and management of undesirable populations, rather than a project of rehabilitation for the sake of the rights of those inside.

The first modern prisons within the USA in the early 1800s were deemed complete failures for some of the same issues that exist today. Due to

quick overcrowding, the prisons were up against the rapid spread of disease, riots, and escapes as well as severe mental break down among the individuals inside (Rubin 2018). This led to the expansion of more prisons, bigger prisons, to address the large number of arrests. Some groups advocated for the closure of such horrible establishments, but the project for a perfect prison became the focus of attention, rather than questioning the endeavor altogether.

Prisons today continue to focus on retributive justice, or an approach to justice focused solely on the punishment and suffering of the offending party. A successful carriage of justice takes the form of a guilty verdict and a sentence with little regard for how that sentence will affect the convicted person, their family, the victims, the staff, or the community at large. After centuries of isolating the body to bend the soul or spirit into submission, the detrimental effects of a prison sentence on the mind, body, and soul of all involved are well documented and undeniable. But what could be done instead? This entry is an introductory exploration of prisons and the possible – a possible that looks to build a more just and equitable society, even in the midst of harmful actions. One could certainly reflect on the darkest and most cruel possibilities for a prison, but that would be best reserved as an entry of its own.

It should be noted that the Western conceptualization of the prison was exported to many non-Western countries through colonialism and other points of contact, but its evolution over time changed within each context. For more on the history of prisons in Africa, Asia, and Latin America (Dikötter and Brown 2018).

Defining Characteristics: Custody and Care in Exception

The defining characteristic of prison is the deprivation of an individual's liberty in custody. Custody refers to the restriction of someone's activities and the suspension of certain rights, most commonly due to one's alleged, certain, or eventual commitment of a criminal act.

A crime is an action that is considered as causing harm or against social norms under the law (local or national) and can be punished under the law. Criminalization has two definitions, one focused on the criminalization of the act, and the other on the criminalization of a person or group. The first is the process of making *an action or object* illegal and punishable by law. What is deemed criminal or illicit depends on each context. For example, in some US states, the recreational consumption of certain amounts of marijuana is legal, while in others this action is a criminal offense punishable by a prison sentence. The second definition refers to the process of deeming *a person or group* criminal by making their activities illegal. For example, the criminalization of opium in the USA did not begin with the prohibition of the substance itself. The first laws against opium outlawed the smoking of the substance, a practice particular to Chinese immigrants at the time.

The same practice can also be seen in the sentence disparity between crack and cocaine. As part of the US “War on Drugs,” the Anti-Drug Abuse Act of 1986 introduced mandatory minimum sentencing for the use and possession of illicit substances. However, crack cocaine which was the cheaper substance was met with harsher punishment. While possession of 5 g of crack cocaine would result in a 5-year sentence without parole, it would take 500 g of powder cocaine to be given the exact same sentence (Britannica 2020). This 100:1 disparity led to a massive spike in the incarceration of low-income communities predominately comprised of African Americans and other people of color. Panic from the media also called for increased policing in these areas, ignoring the detrimental effects incarceration has on individuals suffering from addiction. Even though cocaine is prevalent in White and affluent circles as well, people of color and individuals in low-income areas were and continue to be criminalized at much higher rates. The Fair Sentencing Act passed in 2010 eventually reduced the ratio to 18:1, but many experts question the legitimacy of the gap altogether.

Regardless of where a person has been detained, the deprivation of liberty itself looks

very similar across contexts. The pertinent detaining authority takes custody of the person in question, who is assigned to remain in a closed structure and confined to a limited space. That space could range from a small solitary cell in a police station, a shared dormitory in a juvenile facility, or an entire village-like compound in prison. The rule remains the same – one cannot step outside of the established boundary set by prison authorities. Common facilities include sleeping quarters, areas for eating/cooking, health services, bathrooms, and recreational spaces, each of which can be individual or communal.

Accompanying the custodial characteristic of prisons is a second characteristic – a counterpart of custody: care. Duty of care is a legal concept that obliges a certain individual or entity to offer certain protections and provisions for people they are responsible for, or people under their care. Political scientist Joan Tronto conceptualizes care in its most basic form as the acknowledgment and provision of fundamental goods and services to those who cannot fulfill their own needs (Tronto 1993). Once a legal authority has taken someone into custody, they have also taken away that person’s ability to meet their basic needs – food, water, shelter, clothing, health care, etc. Prison authorities therefore have an obligation to meet their duty of care to people in their detention facilities by protecting the lives and meeting the needs of those under their charge. This is not to say that providing basic care is done in a caring or benevolent way necessarily.

One might ask why define prisons by custody and care and not by punishment or rehabilitation. The main reason for this conceptualization lies in legal obligations and measurability. Punishment and rehabilitation are extremely subjective goals, and there is no widespread consensus on what successful punishment or rehabilitation look like. Prisons are also not liable for failing to punish or rehabilitate someone enough, or at all. Yet, minimal levels of custody and care are mandated by laws and social norms. Adherence to these standards may not always be met, but failure to do so can leave an institution liable to legal and social ramifications on the local, national, and international stage. This conceptualization grasps the

core of carceral action and represents the interests of society and the individual.

In terms of authorities implicated in penal custody and care, one must consider the following: lawmakers define the law which defines crimes and sometimes establishes sentencing laws; law enforcement arrests people allegedly committing acts against the law; the courts decide a person's innocence or guilt as well as their sentence when not predetermined by law; and agencies such as prisons, probation offices, and the like are responsible for carrying out sentences. Acknowledging these roles and institutions illustrates the complexity of prison ecosystems and the challenges to change them. Even so, it also offers multiple potential points of analysis for rethinking what is possible within these systems.

The primary document that delineates the minimal standards for custody and care is the Mandela Rules, or the UN Standard Minimum Rules for the Treatment of Prisoners. Named after the first Black South African president, Nelson Mandela, who himself was incarcerated for 27 years, these rules "set out what is generally accepted as being good principles and practice in the treatment of prisoners and prison management" (Mandela Rules, 7). It covers rules on issues of living conditions, food, access to health care, disciplinary sanctions, and others to ensure humane treatment behind prison walls. Other UN rules protecting specific populations and situations in detention include: "The Bangkok Rules" on the treatment of women, "The Beijing Rules" on the treatment of adolescents, and "The Tokyo Rules" on non-custodial measures. The Convention Against Torture and Other Cruel, Inhuman, or Degrading Treatment or Punishment (CAT) is another guiding document that monitoring bodies can use to investigate and document possible torture or ill-treatment in detention.

Why the need for minimum standard rules? Because prisons and those within often fall within a space of exception, Carl Schmitt's state of exception, later elaborated by Giorgio Agamben, refers to a government or ruling authority's ability to act outside the law and suspend rights during exceptional circumstances such as a natural disaster or security threats (Agamben 2005).

Incarceration is an embodied state of exception in that a certain lack of adherence to minimum standards of custody and care by government authorities is socially acceptable and can be overlooked. Additionally, the stigma that follows upon release continues to deprive individuals access to rights and services. In many countries, the presence of an arrest or criminal record bars one's access to housing, education, jobs, welfare programs, and other services. This is not to say that there are not cases in which such temporary or permanent restrictions may be necessary for a victim's or the public's safety, but most cases do not fall into this category. These barriers, and the stress from navigating these barriers, can be the very reason someone (re)turns to illegal activities. Pushing people in detention further down the priority list is the historically low allocation of funds to prison budgets. Prisons are expensive endeavors. Trying to provide adequate food and living conditions alone costs a lot of money, not to mention educational programs, job trainings, and health care. Unfortunately, many prisons rarely receive enough funds to do so due to strong public opinion against the investment in people they consider dangerous or undeserving. As much as one tries to meet the most minimum standards, the resources do not meet the high demand.

State of Prisons Today

Demographics

Exploring what could be possible in prison requires a first look into the current reality. Before delving into the numbers, one must first understand the difficulty of taking stock of the situation – aka the challenges of gathering accurate data on populations. There are three main challenges. First, the number of people in prisons per country changes every day due to new entries and releases. Second, countries that collect the counts receive information from multiple prisons, each with its own methods of collection. Third, there is no overarching obligation for prisons to provide population numbers. And four, it is not always clear who should collect the information. This leads to varying numbers across agencies and

organizations. For guidelines on gathering criminal justice statistics (United Nations 2003). Even with these challenges, experts understand these statistics as only one piece of the puzzle that must be supplemented with further study. The following section provides an overview of the most recent statistics available as well as current trends from the last 10 years.

According to the most recent data collected in 2021 by Penal Reform International and the UN Office on Drugs and Crime, there are an estimated over 11 million people behind bars, an 8% increase since 2010. Of that, over three million are awaiting trial. In at least 14 countries, the pretrial population is as high as 70%. Though percentages differ across countries, most people in detention are serving sentences for nonviolent offenses. Women make up the minority of the prison population, ranging between 2% and 9% across countries. Though they are a small group, the total number of women worldwide has increased by 17% since 2010, and prisons are often unprepared to accommodate women's needs: menstruation, pregnancy, health disparities, and more women than men are the sole caretakers of children and ailing loved ones.

Clear disparities exist between race and class in criminal justice systems. Prison often affects the most marginalized of groups in society with the least amount of political power. People of color, people in poverty, foreigners, and people suffering from mental health challenges are more likely to be perceived as dangerous, more likely to be policed, and must often rely on overworked public defenders who rarely have the resources to provide the best legal defense – if the right to legal defense is provided at all. Challenges to navigate criminal justice systems vary by country, but the struggle to do so with little resources is a common occurrence.

Trends

Though incarceration trends vary by each country and context, three in particular stand out due to their repercussions on people in detention's well-being as well as their prevalence across the globe: privatization, aging, and crimmigration. One of the biggest concerns regarding privatization is

the fact that private entities, by their nature, prioritize profits. Historically, they have failed to adhere to minimum standards in order to save money. However, the discussion goes beyond the growth of private prisons as entities. Countries that once condemned the privatization of prisons – and continue to still do so – have since begun to enter contracts with private companies for services such as communications, transportation, electronic monitoring, and culinary services. The often compromised quality and delivery of such privatized services negatively impacts the welfare of people inside.

The increase in age of people in detention is also cause for concern. Due in part to the handing down of longer sentences and life sentences, prisons must accommodate older populations with increasing health problems. With age, they are developing chronic diseases such as cancers, autoimmune diseases, and dementia. The toll of prison life has stripped away at their immune systems and physical limitations, demanding assistance in going to the bathroom, specialized diets, and life-saving medications. Furthermore, in some cases, the people in prison who rely on loved ones for financial and emotional support are outliving them. Prisons were not built to cater to these growing needs, and many institutions struggle to adapt and find funding to do so.

The final trend, crimmigration, coined by Juliet Stumpf, lies at the intersection of criminal and immigration law. Crimmigration refers to the criminalization of the act of immigrating as well as the behaviors of immigrant populations in order to monitor, detain, and/or deport them. It can impact immigrants in both documented and undocumented statuses as well as asylum seekers. Driving without a license is a common offense that can result in the involvement of both criminal and immigration proceedings. More and more sectors such as education, work, and housing require proof of residence, shutting individuals out from basic services for survival. Once in the criminal justice system, immigrants are often subject to a double penalty – upon completion of their penal sentence, they are eligible for deportation. Though not new, this trend continues to pick up in popularity.

Additional Groups Impacted by Prison

Vital to discussions on prisons and the possible is the role of victims, families, and staff. Each group is impacted by incarceration in their own ways, and they are often forgotten in both criminal proceedings and reform initiatives.

From arrest to release, victims and their families are often left out of criminal justice proceedings. Current forms of justice provide little consideration for the disappointment that comes with a nonguilty verdict or the eventual release of the person that caused them harm. They are also limited to retributive practices and rarely have the option to participate in victim-offender mediations – a well-lauded restorative justice practice which allows the injured party to hold the injuring party accountable for their actions in a safe and structured environment. Victims' and their families' sense of justice, safety, and peace should play a larger role in the justice system.

Families of people in detention often carry immense emotional, social, and financial burdens in regards to their loved one's incarceration. Daily interactions are reduced to short weekly phone calls. Grandparents become caregivers to their grandchildren in old age. Plans for weddings or children or vacations are put on pause. Extra savings go toward court bills, health bills, and provisions not given by the prison. Loved ones may not be behind bars, but they too suffer the effects of the sentence.

Due in part to small budgets, prisons are often understaffed with overworked and underpaid employees. Some do not receive proper training to carry out their duties effectively and within international guidelines. Some struggle to make ends meet. They too can get sick during outbreaks, be affected by the violence and suffering they witness at work, and they too would benefit from changes to the criminal justice system.

Though a more detailed discussion is beyond the scope of this entry, their inclusion is paramount.

Prisons and the Possible

As this encyclopedia demonstrates, the possible is defined and conceptualized in many different

ways. This entry on prisons and the possible examines possibility from the standpoint of Appadurai's ethics of possibility, the "ways of thinking, feeling, and acting that increase the horizons of hope, that expand the field of the imagination, that produce greater equity...and that widen the field of informed, creative, and critical citizenship" (Appadurai 2013). The following section explores scholars', experts', and advocates' humane and hopeful visions of the possible: prison reform, penal reform, alternatives, and abolition. Except for abolition, these terms are used interchangeably and can refer to each other. The conceptualizations provided here are more for clarity and structure at each level of action.

As previously discussed, the law, law enforcement, the courts, and prisons are implicated in the custody and care of people in prison. This provides various points of departure for the possible at each articulation within and between each of these entities. Visions of the possible in prisons start from the inside. Prison reform refers to changes made within the institution of the prison. Efforts to better adhere to the Mandela Rules would be considered prison reforms – expanding living space, providing nutritional meals, increasing time spent outdoors, etc. A commonly cited prison reform is the prohibition or limited use of solitary confinement – the placement of an individual in an isolated cell, with no meaningful human contact. The person in confinement might have contact with a guard multiple times a day for food delivery, but the interaction is devoid of any social exchange. As a disciplinary measure, solitary's intended purpose is to separate someone who is a danger or in danger and to subdue or calm someone. However, studies show that it does not achieve the stated purpose, and that the detrimental effects on a person's mental and physical health are severe. Though the UN considers any duration passed 15 days as torture, some individuals spend years of their sentence completely alone. If confinement during the Covid-19 pandemic has taught us anything, it is that we need meaningful human interactions.

Another important initiative is the implementation of syringe exchange programs. Given the prevalence of clandestine drug use in prisons,

health professionals have taken lessons learned from the HIV/AIDS epidemics to work with authorities to limit the spread of blood-borne diseases such as HIV/AIDS, malaria, and syphilis. Several studies show that these programs are effective at disease prevention and do not lead to increases in drug use inside the prisons (Stöver and Nelles 2003). Though these findings are promising, more research is needed to improve implementation across contexts. Aside from solitary confinement and the introduction of syringe exchange programs, other prison reforms include introducing education and job skills programs, improvements in nutrition, and training prison staff in nonviolent de-escalation strategies.

Penal or criminal justice reform encompasses any proposed changes to practices, policies, or laws within the criminal justice system. Since the law dictates much of the responsibilities of authorities within the criminal justice system, many reforms focus on changes to the law. One such reform is decriminalization of drug use. Decriminalization is the legalization of a substance or behavior once prohibited under the law. Where a behavior is decriminalized, so too is the person or group partaking in it. At current, people who use illicit substances are criminalized and sent to prison where (1) drug use is prevalent and (2) resources are not always available for drug treatment programs. Rather than further isolate those who suffer from addiction, the goal is to acknowledge and treat addiction as a health issue. Portugal has seen great success with this shift, but that success is thanks to the implementation of comprehensive reforms. Decriminalization went hand in hand with health reforms so that when law enforcement and health and social services came across people using drugs, they could refer individuals to more appropriate rehabilitation programs than a prison could provide. More research is needed to understand any unintended consequences of the reforms as well as possible paths forward for other countries to adapt the laws and implement the practices.

Alternatives to prison refer to any measure within the criminal justice system that can be

used to deter criminal activity and avoid a custodial sentence in prison. Alternatives fall under the jurisdiction of the courts, in conjunction with laws that allow these measures. Some of the noncustodial measures listed in the Tokyo Rules include verbal sanctions, monetary penalties, restitution to the victim or a compensation order, probation and judicial supervision, community service, semi-detention (residents are allowed to leave during the day under certain conditions), and house arrest. A particularly popular yet complex example is electronic monitoring. Electronic monitoring involves attaching a bracelet to an individual's body (usually the ankle) in order to track their whereabouts. The two main types of technologies used are radio frequency (RF) and global positioning satellite (GPS). RF monitors someone's presence or absence in a given perimeter and GPS provides exact locations and trajectories of someone's whereabouts, the former being more common than the latter. This practice has grown in popularity among countries looking to address prison overcrowding. On the one hand, wearing a bracelet allows individuals some normalcy to their everyday lives – continuation of work or school, parenting, and caregiving of loved ones – and avoids the detrimental psychological effects of incarceration such as depression, trauma, and self-harm. Electronic monitoring in lieu of a prison sentence can also decrease recidivism. However, some reformers caution that the overuse of electronic monitoring has resulted in net-widening, or an unnecessary expansion of individuals under penal surveillance, usually of marginalized groups, and in recent decades foreigners. This concern does not diminish the utility of and flexibility electronic monitoring offers as an alternative, but it certainly begs proponents to track and mitigate the unintended consequences of its use.

Although definitions vary among abolitionists, abolition is an ideal that calls for the replacement of prisons with systems and programs that address the root causes of crime, poverty, mental health, addiction, trauma, inequality, marginalization, and other societal challenges. Notable leaders of

the abolition movement include Ruth Wilson Gilmore and Angela Davis (see Davis 2011; Gilmore 2022; Kushner 2019). Abolition does not refer to the complete immediate elimination of prisons. It suggests that the frequency and manner in which prisons are used to address societal issues could be reduced and replaced by other means. It favors transformative justice, a form of justice in which not only is the offender held accountable for their actions, but that their actions are understood in a larger context in which systems and norms such as racism, sexism, capitalism, and the like must be held accountable as well. This does not excuse the harm caused, but grapples with the circumstances that facilitated its occurrence. Abolition asks what justice without a prison would look like and how society can mitigate harm in the short and long term in the process.

At the forefront of abolitionist initiatives is the redistribution of public resources. Calls to defund the police are asking for a partial reallocation of resources from police precincts to social services better equipped to address calls related to mental health, poverty, and addiction. For many, this is not a complete discounting of law enforcement as a public service, but police cannot be the only source of assistance or support because they are not trained to handle such a wide range of crises. Some of the social services envisioned do not yet exist and need building from the ground up. How will services be contacted? How will community needs be identified and updated? What training is needed to address community needs? While abolition does examine the viability of preexisting models, it opens a creative space for rethinking new systems and exploring the possible in new and hopeful ways.

Conclusion

As one reflects on the future of prisons and the possible forms they or their replacements may take, initiatives must be formulated comprehensively. Decriminalization of drug use is only

effective when paired with a strong public health care system. Justice is neither restorative nor transformative if it does not include victims, families, and communities. Reducing the number of prisons will leave employees within penal systems without an income. Facing these challenges in creative ways can provide paths forward in pursuance of a more just and equitable society.

Probabilistic Thinking

Laura Macchi, Laura Caravona, Niccolò Aimo
and Veronica Cucchiari
University of Milano-Bicocca, Milan, Italy

Abstract

This entry starts by defining probability, followed by a review of the historical context of probabilistic thinking. It continues with a brief commentary on experimental classical research on probabilistic thinking, heuristics, and biases research program. It then focuses on the main critical perspectives to this paradigm, the frequentist and the pragmatic approaches, which have reinterpreted the so-called cognitive illusions. These perspectives lead to a further exploration of the concept of probabilistic thinking, which opens the way toward a more genuinely psychological and comprehensive conception of “possible” and “uncertain.”

Keywords

Probabilistic thinking · Heuristics and biases ·
Pragmatic approaches · Verbal probabilities ·
Uncertainty and possible

Definition and History of Probabilistic Thinking

Etymologically, the word *probability* comes from the Latin *probabilitas –atis*, expressing credibility and verisimilitude, and from *proba-ae*, in its joint meanings of evidence and commendable. Probability in the sense of the condition of a fact or an event that may occur, or, if there is more than one possible fact or event, the fact or event that can most reasonably be expected to occur. In this sense, it represents the degree (or even the measurement) of the possibility of an event occurring.

In general, from the psychological point of view, the *capacity for judging* is “the power or ability to decide on the basis of evidence” (*Webster’s Third New International Dictionary*). In other terms, probabilistic judgments are based on

tangible data, which act as indications for intangible events or circumstances; we do, however, also produce these judgments in the absence of data (Macchi et al. 1999).

Historical records show that there was no real concept of probability in Europe before the mid-seventeenth century, although the use of dice and other randomizing objects was commonplace. Hacking presents a philosophical critique of early ideas about probability, induction, and statistical inference and the growth of this new family of ideas in the fifteenth, sixteenth, and seventeenth centuries. He invokes a wide intellectual framework involving the development of science, economics, and the theology of the periods, describing the transformations that made it possible for probability concepts to emerge (see Hacking 1975).

Generally speaking, the notion of probability itself gives rise to the problem of the meaning of the actual concept of probability. Both Carnap (1945) and Russell (1948) insisted on the existence of two different and irreducible concepts of probability: Carnap named them *inductive probability* (or *degree of confirmation*) and *statistical probability* (or *relative frequency*), while Russell used the terms *degree of credibility* and *mathematical probability*. The first concept of probability can be characterized as the degree of possibility of a single event occurring (events or facts or states of things or circumstances: “Tomorrow it will probably rain”). The second, fundamental concept of probability is *collective* or *statistical* probability, which deals with classes, species, or quality of events as opposed to individual events. If for n observations the event in question took place m times, m/n is the relative frequency of this class of events: relative, as applicable to n observations. Therefore, statistical probability does not concern individual events, but classes and sequences of events (Popper 1957). We will find these different acceptations of meaning in the various psychological theories of probabilistic thinking, which, consequently, differ in their formulation of probabilistic problems and their interpretation of the experimental evidence that emerges.

In particular, the mathematical acceptance of the concept of probability is to be found in the

study of subjective probability in the Bayesian paradigm introduced to psychology by Edward's famous article of 1954, in which he proposed, for the first time, a fully articulated model of optimal performance under uncertainty for comparing human judgments. The matching of human judgments to normative models was to become one of the major paradigms of research on judgment under uncertainty.

It can be said that the systematic study of probabilistic reasoning and decision-making processes started to merge as an independent discipline in the 1960s. Those were the years in which psychology was differentiating itself from philosophy and carving out a place among the sciences; to this end, to comply with requirements of "scientificity," it integrated the speculative approach adopted by philosophy with the experimental approach, basing this on logic and the theory of probability. This is the formal point of view used by the psychology of thought to evaluate human reasoning, judgment, decisions, thus creating a paradigm which translated in natural language problems from normative theories. Since the early studies in the 1960s, the predominating vision has been substantially rationalistic, from the logistic theory of deductive reasoning to probabilistic reasoning up to Piaget's theory of epistemological genetics on cognitive development. In the beginning, in fact, the first studies offered a vision of probabilistic thought of statistically naïve subjects that complied with the principles of theoretic decision-making and inferential models from the theory of probability (Edwards 1968). A seminal review of studies on adult statistical inference by Peterson and Beach, titled "Man as an intuitive statistician," confirmed this general approach and arrived at the conclusion that "probability theory and statistics can be used as the basis for psychological models that integrate and account for human performance in a wide range of inferential tasks" (1967, p. 29).

Later, two types of factors modified the general orientation of research in this sector. In the field of psychology, systematic errors in responses to logicist theories were identified (see, for example, the Wason's selection tasks 1966). In the field of economics, on the other hand, the physicist and

economist Allais (1953) demonstrated a decision-making paradox regarding the normative theory, revealing its failure as a descriptive model for decision-making. The search for new descriptive models of behavior led to the study of intuitive statistical reasoning modalities, i.e., the way statistically naïve people reason and evaluate the probability of an event in tasks more closely resembling everyday situations (Tversky and Kahneman 1974; Slovic 1972; Janis and Mann 1977; Nisbett and Ross 1980).

It should be noted that from the very beginning the psychology of reasoning was faced with the question of its specific tasks and competences compared to logic first and the theory of probability some decades later, recognizing effective thinking, or how people really think, as its particular sphere. However, this distinction was formulated within a conceptual framework characterized by references to logic or the theory of probability as a psychological model of correct thinking. And so psychology started by auto-imposing a heavy limitation: the assumption of an inevitably depsychologized pre-constituted norm, borrowed from a tradition, however, to which it opposed its novelty and independence (Mosconi 1998).

It is worth noting that the development of formal logic, in fact, became a gradual process of "depsychologization" of logical language and of disambiguating simplification compared with natural language, intentionally pursued and programmatically declared by modern logic. The psychology of thought has inherited this tradition with a counterpoint: the dilemma of errors, the frequency, transversality, and generality of which were considered to be indicative of the structural limitations of the human mind. This tendency to make mistakes translated into the concept of *bias*, indicating a systematic deviation from the norm inherent to the human cognitive system. From this point on, experimental research on reasoning focused on the problem of human error, the incapacity to grasp the deep logical structure (for a review on this issue see Frankish and Evans 2009).

In brief, whereas researchers in the 1960s concluded that probability updating is "conservatively" proportional to normative predictions, in

the 1970s research suggested that people are incapable of following normative rules (Bayes’s rule). Therefore, psychology of deductive and probabilistic thought had to adopt a dualistic vision as a theoretical framework in an attempt to explain both the human capacity for abstraction and correct reasoning and this tendency to the so-called cognitive illusions. As a result, from the 1970s the principal theories of thought were characterized by a dualistic vision that attributes error to thought processes that are different to those that guarantee correct reasoning. “The fundamental computational bias in human cognition would be the tendency toward automatic contextualization of problem (System 1), [...] while System 2’s more controlled processes would decontextualize [...] and would not be dominated by the goal of attributing intentionality nor the search for conversational relevance” (Stanovich and West 2000, p. 659). What has, however, been lost is the complexity of reality, which was seen as an element of interference, clouding the general structure that underlies reasoning; whereas thought is of necessity contextualized, drenched in content, implicit presuppositions, beliefs, intentions, and deals with reality in all its complexity.

The emphasis on the error of probabilistic reasoning, the so-called *biases*, has only been overcome in this area in the last decades. In fact, a process of critical revision has now been implemented, which has permitted taking into consideration the actual representation that people have of assessments and evaluation tasks. As a result, a different interpretation is now possible of answers that are traditionally considered erroneous, and also, in more general terms, of the concept of rationality.

**Research on Probabilistic Thinking:
From *Homo Statisticus* to *Homo Loquens***

Homo Statisticus. A first group of studies focused on tasks that required a revision of judgment in the light of new information. These revisions are compared with optimal revisions calculated by using Bayes’ theorem (Table 1).

The “Book bag-and-poker chip” experimental paradigm has been adopted by numerous authors

Probabilistic Thinking, Table 1 Bayes’ theorem

$p(H E) = p(H) \times p(E H)/p(E)$	
$p(H E)$	Posterior probability, i.e., the probability that hypothesis H is true if evidence E is given
$p(H)$	Base rate or prior probability of H, i.e., the probability that hypothesis H is true
$p(E H)$	Likelihood, i.e., the probability that evidence E is given if hypothesis H is true
$p(E)$	Prior probability of E, i.e., the probability that evidence E will be given whether or not hypothesis H is true. $p(E) = p(E H) \times p(H) + p(E not H) \times p(not H)$

in several variants. In a typical version of the experiment (Edwards 1968), participants were shown two “book bags,” and told that they were filled with red and blue poker chips, the colors being differently distributed between the bags. One bag contained 70% red chips and 30% blue chips, the other 70% blue chips and 30% red chips. The experimenter selected one of the two bags at random (prior probability 0.50) and then extracted a sequential succession of chips from the bag, e.g., 8 red and 4 blue chips. After each chip was extracted from the selected bag, the participants were asked to judge the probability that it was of the predominant color. Most subjects answered in the right direction (0.75), even if, in accordance with Bayes’ theorem, the precise posterior probability would be 0.97.

These results showed a phenomenon called “conservatism” (Edwards and Phillips 1964; Peterson et al. 1965). As their information was updated, the participants revised their posterior probability estimates in the direction of the normative model (Bayes’ theorem). However, their revision was too small. In general terms, humans were therefore defined as *conservative Bayesians*.¹

Homo Heuristicus. How do people reason and make decisions in a world of uncertainty? The

¹As in most Book bag-and-poker chip problems, the starting point of subjective estimation is specifically set by the prior probability procedure, but the point at which participants decide to stop revising their estimate, according to us, seems in most cases not too far from likelihood.

Probabilistic Thinking, Table 2 Biases and heuristics

Biases	Heuristics
<i>Base-rate fallacy</i>	<i>Representativeness, Causal schemas</i>
<i>Conjunction fallacy</i>	<i>Representativeness, Causal schemas</i>
<i>Gambler's fallacy</i>	<i>Representativeness</i>
<i>Overestimation of sample size</i>	<i>Availability</i>
<i>Anchoring effect</i>	<i>Anchoring and adjustment</i>

discrepancy between theory and reality marked the beginning of the exploration of cognitive heuristics that may well characterize our reasoning in everyday life; what Simon called the “study of *bounded rationality*” (1956). Two main approaches, the “Heuristics and Biases program” and the “Frequentist” approach, provided different answers to the open question that Simon posed.

Over almost a decade, there has been a radical change in the representation of humans from intuitive statisticians to more defective versions (Tversky and Kahneman 1973). The search for new descriptive models of behavior has led to the adoption of an experimental paradigm which used tasks closer to everyday life, but far from the previous contexts that typically elicited the calculation of mathematical probability. In this perspective, heuristics were considered cognitive shortcuts that simplify the complexity of assessing the probability of an event but mainly lead to serious and systematic errors, i.e., biases (“Heuristics and Biases” Program, Kahneman et al. 1982) (Table 2).

One of the most studied biases concerns the failure to take prior probability into account when judging the probability of conditional events, called *base-rate fallacy*, a paradigmatic example of which is the *Lawyers and Engineers* problem (Kahneman and Tversky 1973). The participants were divided into two groups, after which they were presented with short personality descriptions drawn at random from 100 descriptions of lawyers and engineers. While one group was told that the descriptions were of 30 engineers and 70 lawyers, the other was told the descriptions were in the

opposite proportion. This information was followed by five personality descriptions that varied in their degree of representativeness of the engineer/lawyer stereotype. The task was to establish the probability that the person described was indeed, i.e., an engineer. The mean of the responses given by the participants in the two conditions did not turn out to be significantly different, indicating that base rate was not considered. According to the authors, the subjects based their responses only on the typicality of the description in relation to the category of engineers (following a *representativeness heuristics*), almost completely disregarding the number of engineers in the sample (*prior probability or base rate*). This evidence seems to demonstrate the weakness of the “intuitive statistician” thesis, highlighting a behavior which is in no way Bayesian.

Anyway, it is interesting to note the degree to which the structure of the *Lawyers and Engineers*’ problem resembles that of the Book bag-and-poker chips (Edwards 1968): e.g., the 30/70 composition of the reference group and the sample of predominating red chips “8 red and 4 blue,” which corresponds somewhat to the representative description. Despite the apparent similarity of the structure of the two tasks, there is a substantial shift of context from the purely statistical to real life, perhaps determining a different acceptance of the concept of probability (from mathematical probability to plausibility, verisimilitude, credibility).

The *heuristic of representativeness* is also invoked by Tversky and Kahneman (1983) to explain another type of error, the *conjunction fallacy*, which has been exhaustively illustrated with the well-known “*Linda*” problem. Participants were presented with the description of Linda, a young, outspoken, and very bright woman. She majored in philosophy, and as a student, she was deeply concerned with issues of discrimination and social justice. The task was to evaluate the probability that, among other things, Linda was “active in a feminist movement,” a “bank teller,” or a “bank teller and active in a feminist movement.” The great majority of the participants considered, erroneously, more

probable that Linda was a “bank teller and active in a feminist movement” rather than just a “bank teller” because of the presence of the adjective “feminist” which is representative of Linda. However, the probability of the conjunction of two events will always be lower than the probability of each of the two constituents.

A strong reaction to this perspective arrived from a different approach to the study of probabilistic reasoning in the second half of the 1990s, in accordance with an ecological perspective inspired by Simon, to whom anyway also Tversky and Kahneman were inspired. According to Gigerenzer and Hoffrage (1995), the difference in prediction between correct probabilistic inference and incorrect intuitive inference is attributable to the *percentage* format with which data are mainly presented, which is comprehensible only to a small group of experts. In the absence of specific training, the human mind, having evolved in harmony with a given environment, would have the ability to make naturally probabilistic estimates only from data in frequentist format, i.e., the natural format of observation of a sequence of events, and not by percentages (the format typically adopted by Tversky and Kahneman), which are fairly recent forms of representing uncertainty (Goldstein and Gigerenzer 2002).

Consider, for instance, a doctor who has to calculate the probability that a person with a given symptom is suffering from a specific disease. Based on his experience, the physician knows that he has seen 1000 people, 10 of whom had the disease. Of those 10, 8 had the symptom; of the 990 not afflicted with the disease, 95 also had the symptom as well. According to the computation of favorable and possible cases: $8 / 8 + 95 = 8$ out of 103. Note that, as clearly shown in the example, there is no need to pay attention to the base rate (10 out of 1000), since this information is already in the hit frequency, and then it is quite difficult to consider this reasoning as a form of Bayesian one.

Furthermore, if the ecological perspective considers only frequencies as a “natural” format, it is also true that the use of percentages expresses and solves a need for cognitive economy, for saving cognitive resources, which is at the basis of the

functioning of inductive thinking: the need to generalize from the particular. Use of the percentages allows a property or characteristic to be extended from a limited set of cases, individuals, or observations (e.g., 10 out of 1000 40-year-old women) to the general population from which the individuals are drawn (i.e., 1% of 40-year-old women). The advantage for our cognitive system is unquestionable: a saving of cognitive resources and an increase in knowledge, inherent in the possibility of being able to make inferences and predictions even on samples to which there is no direct access, as long as they are part of the same population to which the percentage refers.

Homo Loquens. The pragmatic perspective offers a different explanation for biases in probabilistic reasoning, which goes beyond biasing heuristics and frequentist explanations (Macchi 2000; Macchi and Mosconi 1998). This approach is characterized by taking into account the effect of the communicative intent on reasoning, decision making, and problem-solving (Bagassi and Macchi 2016; Hilton 1995; Macchi and Bagassi 2012, 2015; Macchi and Zulato 2021; Mosconi 1990; Politzer and Macchi 2005; Sher and McKenzie 2006; Sperber et al. 1995). Its core assumption is that the representation of a problem stems from what the problem communicates and how, i.e., not just what is literally said but also what is implied and then effectively communicated (i.e., conversational implicatures, Grice 1975). Indeed, communication should provide an adequate understanding of information to promote reasoning. This is particularly relevant for the understanding of statistical and probabilistic data that lay people are able to understand only if it is communicated appropriately (Koehler and Macchi 2004). In other words, the transmission of objective information is a necessary but insufficient condition, since if the speaker/experimenter does not respect the requirements of natural language, their communication may lead to a misleading interpretation.

In the specific area of probabilistic reasoning, considering for instance the base-rate neglect, pragmatic analysis has revealed that the so-called bias does not seem due to the difficulty implicit in Bayesian reasoning but seems to be

caused by a specific formulation of the likelihood (Macchi 1995). The supposed tendency to ignore the base rate in favor of the likelihood would result from a distorted transmission of information induced by how the text of the problem is structured. The transmission modality of the conditional relationships between the various pieces of information constituting the problem would be inadequate because it operates a sort of literal translation of the formal concept into a different language, the natural language, which can be insufficient or misleading.

The well-known experimental *medical diagnoses* paradigm, introduced by Casscells et al. (1978) and Eddy (1982), is an excellent example of this. It is often summarized in the literature as follows:

The probability of breast cancer is 1% for women at age 40 who participate in routine screening. If a woman has breast cancer, the probability is 80% that she will get a positive mammography. If a woman does not have breast cancer, the probability is 9.6% that she will also get a positive mammography. A woman in this age group had a positive mammography in a routine screening. What is the probability that she actually has breast cancer?

Ninety-five out of 100 physicians to whom the problem was submitted gave an estimate between 70% and 80%, which almost coincides with the percentage of true positives, while the Bayesian answer is much lower (7%). The heuristics and biases approach considered this phenomenon as emblematic of the difficulties in Bayesian reasoning; the frequentist approach translated the same problem into natural frequencies to show the effect of the frequentist format, as already said. The pragmatic approach could succeed in providing a coherent response for the emerged contrasting evidence.

Take this specific sentence in the original text: “If a woman has breast cancer, the probability is 80% that she will get a positive mammography.”

This formulation, though quite natural in common language, could not be able to convey the underlying statistical meaning, thus leading to confusion between conditional probabilities: (i) likelihood, i.e., women with breast cancer who have a positive mammography, and (ii) a

posteriori probability, i.e., women with a positive mammography who have breast cancer.

An adequate and more understandable representation of the sentence can be obtained if it is reformulated to read closer to the actual meaning of the information, thus helping to avoid the very common misunderstanding illustrated above:

80% of women with breast cancer have a positive mammography.

This type of formulation has been called *partitive* (Macchi 1995, 2000), as it indicates the set to which the data refers, defining the proportion or subset of the population (women with breast cancer) of which the data represents a part (women with breast cancer who have a positive mammography) and thus relativizing the numerical content (80% of 1%). When such a formulation is adopted, either in terms of relative frequencies expressed in percentages, or in terms of natural frequencies, the independence of the base rate from the hit rate is clear and the relationships between the data can be correctly used. Thus, when adopting the partitive formulation, even without neutralizing the heuristic principles involved or adopting a *frequentist format*, there is a substantial decrease in the occurrence of the fallacy.

According to this view, the improvement in the results following the use of frequentist formulation could be attributed to the presence of this particular information format, the *partitive formulation*, rather than to a more ecological format. This formulation, renamed by Barbey and Sloman (2007) as *nested sets*, can be considered as the linguistic equivalent of a graphical set representation. The partitive formulation is a way of translating a specific language into a natural language, in a task structured partly with a common language and partly with a specialized language. The pragmatic approach, which considers language and thought to be closely interconnected, implies and entails the unavoidable reintroduction of the psychological aspects eliminated from technical-specialist communication by the natural language adopted in the problems studied.

Probabilistic Thinking and the Possible

Among the more recent contributions, another possible key for understanding the inconsistency across research traditions has been provided by Lejarraga and Hertwig (2021). They argue that the core of the problem lies in the changes to the types of experimental paradigms. Starting from Kahneman and Tversky's studies, not only has the content of the problem been brought closer to real-life situations with respect to previous experiments, but there has also been a shift from an experience-based approach (participants directly interact with the environment and sample information sequentially) to a descriptive-based approach (a symbolic representation of the situation is provided, informing the participants about the hypothetical events). The authors claim that first-hand experience can promote appropriate statistical inferences in probabilistic thinking while description does not.

According to the authors, this approach would also be able to clarify why, although natural frequencies are used in descriptive paradigms, they can reflect some of the underlying experience, leading to a better performance. Anyway, what this perspective has still not managed to explain is the effectiveness of using the partitive formulation, as it fits into a descriptive paradigm in which the percentage format can also be used successfully.

All things considered, from a communicative perspective the historical evolution of the approach to probabilistic thinking it seems plausible to consider the hypothesis of a sort of progressive detachment from a mathematical acceptance of probability to a conception of possibility as credibility and verosimilitude. While the Book bags-and-poker chips problem explicitly brings to mind mathematical-statistical inference contexts, the problems formulated after the 1970s that tend to use description of personalities, medical diagnosis and similar scenarios, seem to have switched the conception of the probable to what can be plausible or likely, which may distort and fail to make clear real intention of the experimenters, even to the point of obscuring it (Mosconi and Macchi 2001).

This issue has been explored by revisiting the classic studies conducted on probabilistic reasoning with people trained in logic and mathematics, inviting further speculation about the type of cognitive capabilities of those diversely gifted people who solved the same tasks without such training. A first critical question emerges from an analysis of the results obtained by Tversky and Kahneman (1983) working with *informed* and even *sophisticated* subjects in the field of statistics. Paradoxically, when attempting to solve the well-known *Linda problem*, the majority of these subjects committed the so-called conjunction fallacy. Undoubtedly the fact that people trained in decoupling failed to recognize a relative elementary logical rule such as the inclusion rule, raises questions that need to be addressed. How is it possible that subjects trained in logic or statistics had such difficulty with these tasks? In the absence of an appropriate translation from the logical-mathematical to a natural language code, or of an adequate signaling of the code used, it is only to be expected that the understanding of the task is based on discursive-conversational rules the subject is accustomed to using, that do not necessarily correspond to the logical-mathematical codes (Bagassi and Macchi 2016).

It could justifiably be inferred that this process of interpretation of mathematical probability vs. plausibility and possibility judgment can be strictly linked to how the data in the task is formulated. This is best shown by the evidence in the field of the "Exemplar-cuing theory" (Koehler and Macchi 2004), which states that people attach more weight to low-probabilities when the formulation of the data can easily generate examples in their minds. A recent example has been provided by Aimò and Macchi (in preparation) in a study focusing on the perception of slight probabilities related to the phenomenon of lottery gambling. The aim was to understand if different formulations of the winning chances could influence the probability-assessment, increasing or reducing the willingness to pay in gambling. Three formats were taken into account: (a) *frequency* format "the chance of winning is equal to 1 out of 6 million," (b) *single-case* percentage format "the chance of

winning is equal to 0,000017%,” (c) *narrative* format “imagine a continuous line of lottery tickets connecting Milan to Rome: the chance of winning is equal to stopping in any spot of the road and picking the only winning-ticket.”

Comparing frequencies and percentages, results showed that the first induced a higher willingness to pay. When the hit-rate is expressed as a number equal or greater than 1 (e.g., 1 out of 6 million), it elicits the mental representation of the winning chance, inducing a higher possibility judgment than smaller hit-rates (e.g., 0.000017%), which appears less possible. These results are in line with the Exemplar-cuing theory: the same event can be judged more (or less) possible depending on how the data are formulated, in this case, “1” is exemplar-cuing, while “0.000017” is not. Interestingly, results showed that the narrative format induced the highest levels of willingness to pay. The authors proposed two possible hypotheses to explain the effect of the narrative formulation: (1) it increases the perception of the winning chances through exemplar-cues in the form of mental representations and (2) it stimulates involvement and active participation in the task through gamification. In fact, the narrative format is the one which seems more distant from probabilistic language and at the same time closer to everyday discourse.

The translation of probabilities into common language and everyday scenarios, of which narrative is one possible example, has been well studied in the format of verbal probabilities. Verbal probabilities are verbal expressions of probabilities that provide a vague estimate of the likelihood of an event (Brun and Teigen 1988; Teigen and Brun 1997, 2000, 2003), such as “a chance,” “very likely,” and “plausible.”

An established body of research has focused on the possibility of translating verbal probabilities into numerical ones and vice versa (e.g., Reagan et al. 1989), showing that it is possible to translate words such as “very likely” into estimates, but at the same time, these estimates are so different among people that they can represent a potential communication problem (Teigen and Brun 2003). A probability approaching certainty should be defined as “highly probable” or “almost certain,”

probabilities around 50% as “uncertain” (Teigen and Brun 2000). In actual fact, verbal probabilities can also be used to convey a meaning that may deviate from the mathematical datum, depending on the *speaker's intention* (the choice of term has pragmatic implications) and prior expectations. Furthermore, verbal probabilities are more *directionally accurate* than numerical probabilities, because they are formulated in order to directly refer to the potential presence or absence of a given event. Hohle and Teigen (2018) focused on the effects of the so-called “single-bound probabilities” combined with a directional preposition, such as “over 30%” or “under 50%.” These formulations, which are common in everyday life, convey more information than simple numerical data. If the expression “over 50%” is used, it would be logically correct to assume that the exact value could be anywhere between 50% and 100%; however, it is interpreted as a value roughly located around 60%. Again the logical acceptance of probability could diverge from the psychological one, with broad implications for the representation of the possibility of events.

Summary

In everyday life, uncertainty is a condition with which people must deal. The expression of this uncertainty is the probability. Probabilistic thinking and how people talk about the probability of events shape what they do in the present (and will do in the future). Studying how people reason, understand, and use probabilities is fascinating and relevant. Several approaches over the years have proposed opposing views about human probabilistic reasoning. Researchers in the 1960s concluded that humans are intuitive statisticians, able to evaluate probability in the Bayesian way. From the 1970s, with new studies recreating real-life contexts, the view changed completely, considering a defective version of humans, guided by heuristics rather than normative thinkers. Several paradigms tried to explain this discrepancy. As discussed, the reference to an extra-psychological normative criterion (logic and the theory of probability) in evaluating human reasoning remained

unchanged for a long time. Only in recent decades, the study of probabilistic reasoning focused on the actual representations that people have of probabilistic tasks. Studying probabilistic reasoning means dealing with a complex reality: how people take into account probability in real life is, in fact, subject to the influence of context, expectations, prior knowledge, speaker's intentions, and so on. From a communicative perspective, it seems possible to consider the hypothesis of a progressive shift from the mathematical meaning of probability towards a concept of possibility as credibility and verisimilitude.

Problem Finding

Roni Reiter-Palmon and Sanaa Ahmed
Department of Psychology, University of
Nebraska at Omaha, Omaha, NE, USA

Abstract

Problem finding or problem construction is commonly seen as the first step in creative problem-solving. Problem construction consists of two main aspects. The first aspect focuses on the identification of problems in the environment. The second aspect of problem construction focuses on the structure and description of a problem in order to then create a solution. The problem construction process most often occurs quickly and automatically; however, actively engaging in problem construction has been linked to an increase in creativity. Additionally, problem construction has been associated with creativity across a wide range of domains. There are a variety of factors that may affect problem construction, such as expertise and personality variables, as well as the amount of time or information provided to the problem-solver. While problem construction tends to be automatic, training

in problem construction or instructions to actively engage in problem construction increase creativity. Engaging in the problem construction process takes time and requires effort on the part of the problem-solver. Problem construction provides a road map for the possible. Goals identified in the problem construction process relate to what is possible, which constraints relate to what is impossible.

Problem finding · Problem definition · Problem construction · Creative problem-solving

What Is Problem Finding?

When studying the realm of creativity, a common avenue of research is the cognitive processes associated with creative problem-solving and creative thinking (see ► [“Creative Problem-Solving”](#)). Within many of these cognitive process models, problem finding or construction is frequently listed as the first step (e.g., Guilford 1967; Mumford et al. 1991). There are many variations of the term problem construction, including problem definition, problem discovery, problem identification, problem framing, and problem finding. While the underlying definition stays fairly consistent, each term has its own specifications; in order to prevent potential confusion, this entry will use the term problem construction. Problem finding consists of two key facets, as pointed out by Reiter-Palmon and Robinson (2009). The first focuses on problem identification and recognizing opportunities in the environment even when those have not been explicitly presented to the individual solving the problem. The second facet focuses on structuring and describing the problem in a way that provides the individual with a basis to develop a solution.

Problem construction is particularly important when problems are ill-defined. This is because a main aspect of ill-defined problems is that problems are not clear or presented, rather they need to be identified. Further, an ill-defined

problem lacks structure and definition, thereby creating a good environment to engage in problem construction.

The Problem Construction Process

A vast majority of problem-solving models list problem construction as the first step in the process. Despite this, there are not many models of the actual problem construction process. Initial models suggested two phases of problem construction, starting with problem recognition followed by problem definition (Basadur 1995; Guilford 1967). A more comprehensive model detailing the process of problem construction was proposed by Mumford et al. (1994); see Fig. 1. In this model, problem construction begins with an event which in turn must be perceived. The first step in the model proposed by Mumford et al. (1994) corresponds to one aspect of problem construction, namely, identifying opportunities in the environment or problem anticipation. The cues observed in the environment trigger problem representations, which are knowledge frameworks or problem representations, and contain four types of information: the goals or outcomes associated with the problem-solving effort, information required to describe and solve the problem, procedures and operations executed in order to solve the problem, and any limits or hindrances restricting the problem-solving effort. Problem representations are developed based on past problem-solving efforts (Holyoak 1984).

If a particular problem representation has been linked previously to a specific cue, it will be activated again upon observation of that cue (Mumford et al. 1994). However, ill-defined problems typically have a variety of cues that are more intricate. These cues can potentially be linked to several different problem representations, meaning multiple problem representations may be activated. Fewer problem representations and even a single problem representation may be activated, the more well-defined, simple, or structured the problem is. If an individual is presented with a problem that is similar to a

Problem Finding, Fig. 1 Problem construction model. (From Mumford et al. 1994)

problem he or she previously solved, the problem representation linked to the original problem-solving effort will be activated. If multiple problem representations are activated, the problem-solver may take components of the different problem representations and combine them into a novel problem representation. The outcome of this novel problem representation may be a more creative definition of the problem and by extension would lead to a more creative solution.

The problem construction process described by Mumford et al. (1994) has a number of important implications. First, problem construction will occur quickly or automatically in the majority of cases. This includes routine problems, problems that have been solved before, and problems that resemble previously solved problems. An individual will only actively engage in problem construction if a problem varies from previously confronted problems or if it activates multiple problem representations. Second, the

problem construction process contains both convergent and divergent aspects. Incorporating elements of several problem representations into a novel representation is a convergent process. Conversely, the activation of multiple problem representations is a divergent process (Baer 1988; Reiter-Palmon et al. 1997). It is also important to note that knowledge plays a key role in the problem construction process as well. What problem representations are activated is based on similarities between observed cues in the environment and prior problem representations (Mumford et al. 1994). Making connections of this manner indicates that some knowledge is essential to successful problem construction.

Importance of Problem Construction

Problem construction has been repeatedly associated with creativity in a variety of domains. The seminal study on problem construction was conducted by Getzels and Csikszentmihalyi (1975). In this study, students of art were asked to paint a still life painting. They were provided with a large number of objects to choose from and were observed throughout the entire process, from selecting and composing the objects all the way to the completion of the painting. The paintings were then assessed for aesthetic value and originality by instructors. Problem construction behaviors, such as number of unusual objects selected, how long it took the student to arrange the objects, and so on, were evaluated. It was found that problem construction predicted the aesthetic quality and originality of the resulting painting.

Furthermore, problem construction measures were foretelling of artist success measured at two different points in time, 7 and 18 years later.

Other research suggests that problem construction is predictive of creative accomplishments as well as creative problem-solving in day-to-day problems. More importantly, problem construction is predictive of creativity above and beyond other predictors, including intelligence and divergent thinking. Additional work in this area has proposed that individuals higher in creativity

spend an increased amount of time and effort on problem construction than individuals lower in creativity (Okuda et al. 1991; Rostan 1997; Reiter-Palmon et al. 1998). More recently, a meta-analysis revealed that, compared to other cognitive processes, problem construction had the strongest effect on creativity (Ma 2009). As such it appears that creative individuals tend to engage in more effective problem construction.

Factors That Affect Problem Construction

The literature on problem construction demonstrates that it is integral to the creative problem-solving process. It is important to understand what factors influence problem construction and by extension may have an effect on creativity. A great deal of research has shown that active engagement in problem construction increases the creativity of both the process and the solution to the problem (Redmond et al. 1993; Reiter-Palmon et al. 1997). More recently, perspective taking during the problem construction process has been demonstrated to enhance the process (Vernon and Hocking 2016). Additionally, a meta-analysis on creativity training revealed that training in problem construction had an improved effect on creativity, so much so that it is one of the best methods for improving creativity (Scott et al. 2004).

Prior studies have indicated that problem construction ability was associated with more novel problem construction and more creative solutions (Reiter-Palmon et al. 1998; Runco and Okuda 1988). Other studies have indicated that individuals with higher levels of creativity, including experts, spend more time on the problem construction phase. However, the relationship between expertise and problem construction is not clear. Compared to beginners, experts typically have more problem representations that can be used to help define the problem and spend more time on problem definition as a whole. Experts may evaluate novel problems as similar to problems they have dealt with in the past, and thus may have a main problem

representation. It is also possible that experts are able to actively identify potential constraints, thereby leading them to discover particularly creative solutions.

There are a variety of individual difference variables that have been associated with problem construction. Personality variables linked to problem construction include openness, flexibility, tolerance for ambiguity, and creative self-efficacy. Additionally, individuals who view themselves as creative tend to engage in effective problem construction. It is likely that individuals who are more motivated to engage in problem construction will do so because actively engaging in problem construction is a time-consuming and arduous activity. In addition to individual difference variables, contextual variables also influence the problem construction process. The degree of consistency of information in a problem also influences problem construction. Although well-defined problems tend to contain consistent information, ill-defined problems typically include a wider variety of cues that may be inconsistent with one another. Conflicting cues and inconsistent information in problems have been linked to higher levels of creativity and originality of the solutions. This may be due to the effect the contradictory information has on the variety of problem representations activated, which are then integrated into a new problem representation (Mumford et al. 1994; Reiter-Palmon et al. 1997).

A recent meta-analysis proposed that the connection between the problem construction process and creativity could be dependent on the measure of creativity used as well as the domain (Abdulla et al. 2018). This is consistent with previous findings demonstrating that domain and task effects have a variety of outcomes regarding creativity.

Problem Construction and the Possible

Problem construction, at its core, is a process by which the creator identifies the possible. As noted previously, problem construction is determined by

problem representations, and an important aspect of the problem representation is the goal of the problem-solving effort. As a result, inherent in the problem construction process, is the identification of the possible, through the identification of a desired goal. In addition, the problem representation includes constraints or restrictions. These are specific actions or outcomes that cannot be achieved. As such, these represent the impossible. However, it is important to note a critical caveat. While restrictions and constraints indeed represent those actions that cannot be taken, and those goals that cannot be achieved, in many cases that is not necessarily the case. These restrictions may be a result of underlying assumptions that have not been verified, or based on past problem representations, and not applicable to the current problem in the current situation.

One important aspect of creative problem-solving is indeed the identification and question of such assumptions. When individuals attempt to solve problems when they assume these restrictions, which do not really exist, they are in fact restricting the options that they have to solve the problem – they are restricting the possible. In questioning assumptions, making implicit assumptions more explicit is a key to constructing problems more creatively and achieving creative solutions. By questioning these assumptions, the creator will be able to identify true restrictions and remove those that do not truly apply, therefore increasing the potential and possibilities. However, it is important to note that constraints can be facilitative of creativity (Stokes 2014). In fact, under some circumstances, when there are not too many constraints, and when the constraints are not too severe, constraints have been found to be beneficial. Further, constraints can directly indicate that creativity is needed, not necessarily to solve the problem, but to overcome the constraints imposed. In that respect, constraints themselves may open certain possibilities, even as they close off others.

Experimental manipulation to engage in problem construction also creates conditions that call participants to think about the possible. The typical instructions following Baer's (1988) approach, ask participants to "restate the problem

in as many ways as you can, starting with How can I or How can we". These instructions require participants to think about goal states – which are the desired goal(s) for solving the problem at hand. As ill-defined problems tend to have multiple possible goals, this typically results in multiple restatements targeting different goals. The purpose of this manipulation is indeed to facilitate the generation of multiple goals, which in turn would facilitate the activation of multiple problem representations. The activation of multiple problem representations would hopefully result in a new problem representation, which would result in a more creative solution. In this case, the purpose of the manipulation is to increase the possibilities. That said, while in many cases the effect of these instructions is clear, and results in improved creativity, that is not always the case. Recent research suggests that the quality of the active engagement in the problem construction process is important. Generating multiple restatements that are conflicting (as opposed to complimentary) and acting on those when solving the problem is critical for creativity. That is, while it is possible to think about multiple goals, individuals may focus on only a subset of the goals generated, because it is easier. When goals are conflicting, the number of potential solutions that would effectively solve the problem is reduced (Butler et al. 2003). Further, because solving for conflicting goals is more difficult, individuals may focus on identifying an easier solution even if it ignores all the potential goals. As such, possibilities both increase and decrease at the same time. The number of possible effective solutions for multiple and conflicting goals is smaller (therefore showing a decrease). However, addressing multiple goals increases the possible – as multiple goals are taken into account and not ignored.

As this section suggests, the role of problem construction is important for creativity, but also for understanding and determining what is possible and what is not. Problem construction through the use of goals and constraints in the problem representation creates a place for the possible.

Problem Redefinition

Roni Reiter-Palmon¹ and Vignesh R. Murugavel²

¹Department of Psychology, University of Nebraska at Omaha, Omaha, USA

²University of Nebraska at Omaha, Omaha, USA

Abstract

This entry examines the process of problem redefinition. Problem definition is discussed as it fits into the larger creative problem-solving process. Specifically, the distinctions between problem redefinition and problem definition are detailed. A formal definition of the problem redefinition process is formed from these qualifications. Theoretical and empirical works on redefining problems to produce creative solutions are examined to better understand the utility of the redefinition process. Literature from organizational science, social and cognitive psychology, and design thinking is reviewed to elucidate the problem redefinition process. Both individual-level and group-level problem redefinition processes are considered. A brief discussion of research on goal change is provided to further describe how and why problem redefinition occurs. Finally, the

role of the possible is discussed to capture the essence of problem redefinition.

Keywords

Creative problem solving · Creative process · Problem definition · Problem redefinition

What Is Problem Definition?

Rhodes (1967) has suggested that research on creativity falls into one of four different categories, known as the 4P model of creativity. According to Rhodes, creativity can be understood by the Product, or the outcome, the Person, which involves personality and motivation, Process, which focuses on the cognition or thinking processes associated with creativity, and Press, or the environment. Multiple models of creative cognition or creative problem solving exist (e.g., Dewey 1910; Guilford 1967; Mumford et al. 1991; Newell and Simon 1972; Sternberg 1986). It is noteworthy that all these models include problem definition or a similar construct (e.g., problem findings, problem construction, problem identification, problem discovery). An important aspect of this first step of creative problem solving is problem definition, that is, structuring the problem, defining what the problem is and is not, and defining the problem relative to a goal state (Reiter-Palmon and Robinson 2009). The characterization of the problem definition process makes it clear that it includes an evaluation of a desired goal state, an existing or potential gap, and envisioning the possibilities that exist. These possibilities include not only the desired goal state, but also the various approaches to reach the desired goal state from the current state of affairs (Basadur et al. 2000). The possible routes to a creative solution, product, or outcomes are considered in the problem construction process.

What Is Problem Redefinition?

Problem definition is seen as the first step in creative problem solving, followed by other processes such as idea generation and idea evaluation. However, the creative problem-solving does

not always occur in a fixed progression of processes (Mumford et al. 1991). Each of the core creative processes incorporates outcomes from earlier processes. For example, idea generation uses problem structures formed in problem definition to develop a set of possible ideas (Reiter-Palmon and Hullsiek 2010). Idea evaluation uses criteria identified in problem definition and idea sets formed idea generation to identify the best idea for implementation (Mumford et al. 2002). Although these core processes form a continuum, creative problem-solving is not linear. Individuals can cycle back to earlier processes when they encounter difficulties in any process. For instance, if the idea generation process is not successful or idea evaluation reveals that none of the ideas generated can be implemented, earlier processes may be revisited. When this occurs, problem-solvers may return to the original problem definition. Under these conditions, the problem-solver is then likely to re-evaluate their previous definition of the problem and determine if that problem definition still applies or should be revised. Problem redefinition occurs when the original problem definition has been changed to address the deficiencies or difficulties encountered in the creative problem-solving effort.

Model of Problem Definition and Redefinition

Problem definition and problem redefinition are particularly important when problems are ambiguous and ill-defined. When problems are well-defined, the problem is delineated for the problem-solver. There may be no need to define the problem, identify criteria and goals, and form a structure to generate possible solutions. The problem-solver can proceed to generating ideas. When problems are ill-defined, it is not clear what the problem is, or the problem can be viewed in multiple ways. Ill-defined problems compel problem-solvers to engage in problem definition to produce creative solutions (Reiter-Palmon 2018). In a similar vein, unforeseen difficulties in the creative problem-solving process may compel problem-solvers to redefine the problem.

A problem construction model proposed by Mumford et al. (1994) can be particularly helpful in understanding factors that influence problem definition and redefinition (see entry for Problem Finding). The model proposes that individuals must attend and perceive cues in the environment, which indicate that there is a problem to be solved. These cues also provide information on the nature of the problem, and therefore dictate how it should be defined. Environmental cues in turn trigger problem representations. Problem representations are memory structures stored in long-term memory and are based on past problem-solving efforts (Holyoak 1984). As a result, past experiences have a significant effect on how problems are defined and constructed. When multiple problem representations are activated and a single problem representation cannot be used, the problem solver must find a way to create a new problem representation. New representations include a mix of the elements from the activated problem representations. These compound representations will likely result in a more creative way to define the problem (for a review of the full model see Mumford et al. 1994).

While a theoretical model of problem construction and problem definition exists, understanding when and under what conditions individuals choose to redefine the problem is more limited. In a model of creative processes, Mumford et al. (1991) outlined that a return to problem definition results from a process of solution monitoring. During monitoring a problem-solver seeks indicators of the implementation success of an idea. According to Mumford and colleagues, monitoring can lead to a reconsideration of the approach to an idea's implementation or can lead to a return to problem definition. The authors propose that the action of returning to previous processes depends on the solver's skill in evaluating indicators, self-awareness, and the type and validity of feedback from the implementation environment.

Although Mumford et al. (1991) decreed that redefining a problem is a noteworthy part of the creative process, their model does not fully detail how or why redefinition occurs. Design thinking provides some insight into this redefinition process. One important tenet of design thinking is

that of prototyping (Kelley et al. 2001). A prototype allows the designer to try out the solution to the problem quickly, and identify shortcomings. This in turn will lead to revisions in the creative problem-solving process. While in many cases the prototype will suggest that a solution requires modifications or a new solution is needed, there are cases where prototyping can point to deficiencies in how the problem was originally defined, and therefore lead to problem redefinition (Kelley et al. 2001; Reiter-Palmon and Paulus 2020).

There is some limited empirical work on problem redefinition. Work by Medeiros et al. (2018) focused on the role of introducing constraints before various processes such as problem definition, idea generation, and idea evaluation. Constraints show a complex relationship with creativity, sometimes hindering creativity, while at other times facilitating creativity (Amabile et al. 1986; Medeiros et al. 2014). Medeiros et al. (2018) hypothesized that the timing of when constraints are introduced is important as it would force participants to redefine the problem. The results indicated that when participants received constraints prior to idea generation, but after defining the problem, they revised the problem definition, which resulted in more creative ideas. In addition, receiving constraints later in the process resulted in lower creativity compared to those receiving constraints earlier in the process. This may be a result of the difficulty in revising the problem definition later in the process when a solution is already emerging and being developed. Other research also supports the notion that early evaluation, which likely results in change to the problem definition, results in increased creativity (Fürst et al. 2012).

Reiter-Palmon and Harms (2018) have specifically set out to study the effect of revisions on creativity. The study included two manipulations: (1) Problem definition – participants were explicitly asked to define the problem before solving it or proceed directly to the solution generation phase, and (2) Revisions – participants were asked to revise their problem definition and solution, or they were not. Solutions were then evaluated on their quality, originality, and complexity. Those in the revision condition generated

solutions that were of higher quality, more original, and more complex compared to those that were not asked to revise their ideas.

Intraindividual Sources of Problem Redefinition

While problem redefinition can occur within the individual, when that person returns to and modifies their original definition of the problem, another way problem redefinition can happen is across individuals. There are two ways in which this can occur. The first type of intraindividual problem redefinition occurs when an individual does not accept the way others define the problem, instead choosing to define it differently. An example of this is the discovery of penicillin (Gaynes 2017). This discovery was credited to a “chance event.” However, when others saw as experiments that did not work, Fleming was interested in the why – he redefined the problem from a failure of the experiment to trying to understand why the bacteria did not grow in the petri dish. Penicillin was discovered as a result of a choice to redefine a problem.

A second way in which intraindividual problem redefinition can occur is when teams work together to define a problem in a new way, one that integrates multiple perspectives and problem definitions across individuals. As indicated, problem definition is based on past problem-solving experiences. This poses a significant issue for teams engaging in creative problem-solving, especially diverse teams. As a result of the diversity (demographic and/or functional) individual team members will define the problem differently based on their different past experiences. Cronin and Weingart (2007) coined the term “rGap” to denote differences in how individual team members understand the problem and define it differently. Weingart et al. (2005) found that teams with larger rGaps tend to have difficulty during problem definition, leading to poor cognitive integration as a team and lower creativity. However, Weingart et al. (2008) found that when teams identify the discrepancies early and use them to communicate about alternative pathways to

solving the problem, creativity is higher for teams with larger rGaps. The results from these two studies suggest while different perspectives on how the problem is defined exist in teams, when team members discuss the different perspectives, solutions to the problem are more creative. The integration of diverse perspectives and conceptualization characterizes the team problem redefinition process.

Works by Leonardi (2011) and Gish and Clausen (2013) suggest that team members are frequently not aware of these discrepancies in perspectives and problem definition. Further, both studies found that team members were more likely to experience conflict and disagreement as a result of having these discrepancies. However, when team members were encouraged to discuss how problems were defined, the diverse teams were able to overcome the differences, integrate the diverse perspective, and redefine the problem based on that integration. More creative solutions followed as a result. Finally, Toader and colleagues (Toader et al. 2019; Toader and Kessler 2018) suggest problem redefinition results in more creative ideas when teams are diverse and team members have dissimilar problem representations. That is, when team members discuss, integrate the different ways in which they define the problem, which results in problem redefinition, the outcome is increased creativity of the solution. Overall, the studies cited indicate that when teams work on a creative problem-solving effort, individual problem definitions need to be modified and redefined to allow for the integration of multiple problem definitions.

How and Why Problems Are Redefined

As problem redefinition involves a reconsideration of goal states, literature on multiple goal pursuit and goal adaptation may help explain why individuals decide to return to their original problem definition. Theories of motivation (e.g., expectancy-valence theory, goal-setting theory, and control theory) suggest that the instigator of

goal change is perceived discrepancy between what is expected and what actually occurs (Campion and Lord 1982; Hollenbeck and Klein 1987; Locke et al. 1988; Lord and Hanges 1987; Wanous et al. 1983). A model of goal adaptation by Swait et al. (2018) proposes that adapting the weight one places on prior goals depends on the goal's attainability. More attainable goals are given more significance. Realized goal-outcome discrepancies may highlight which portions of an ambiguous and ill-defined problem is solvable after feedback from the environment is received. The problem redefinition process might be used to reprioritize goals by attainability.

Beyond reprioritization, problem redefinition may change goals in problem structures altogether. Research by Wieber et al. (2014) suggests that by default, people change their actions, not their goals, when there are discrepancies between expected and actual outcomes. However, the authors found that when people deliberate over pros and cons when forming goals, they are likely to forego plans related to resolving original goals and readdress the initial goals themselves. According to Wieber and colleagues, deliberating pros and cons is associated with being in a "why" mindset. This mindset points out that goals and objectives can be flexible and alterable in dynamic situations. In the context of creative problem solving, these findings imply that active engagement in problem definition might allow people to readdress goals and problem objectives when necessary. Problem redefinition may be a natural consequence of problem construction when discrepancies between expected and actual outcomes are perceived.

Kernan and Lord (1990) examined these discrepancies alongside goal reprioritization in multiple-goal environments. Problems that can be solved with a creative idea often are ambiguous and involve multiple objectives (Mumford et al. 1991; Reiter-Palmon 2018; Schraw et al. 1995). As such, Kernan and Lord's (1990) findings can speak to changing goals in the creative problem-solving process. The authors found that people prioritize goals based on differences between their expected outcomes and feedback

from the environment. Factors that influence goal reprioritization include the value one places on producing a creative solution and beliefs about effortfully accomplishing a goal. That is, a person might change their creative goals and paths to accomplish those goals when they believe producing a creative solution is important and when they believe that producing a creative solution is attainable. Indeed, understanding what is and is not possible is key to evoking problem redefinition.

Problem Redefinition and the Possible

A key aspect of problem definition and problem redefinition is the focus on what is possible. Problem representations, which are the building blocks of problem definition and redefinition, contain elements that focus on potential but not guaranteed resolutions. Problem representations include goal states or desired outcomes, which identify the possible. In addition, problem representations also incorporate constraints or restrictions, which focus on aspects of the problem or environment in terms of what cannot be done or cannot be achieved. The possible and impossible are found in problem definition and problem redefinition. However, it is important to note that while restrictions and constraints indeed highlight the actions and goals that cannot be resolved, the development of a solution may not always be impeded. Problem-solvers may look for ways, sometimes creative ways, to overcome these constraints. In addition, constraints may not necessarily be present as the problem-solver understands them. That is, constraints may be a result of underlying assumptions that have not been verified or based on past problem representations. These constraints may not apply to the current situation. In both cases, working around the constraints or questioning assumptions may provide a way to redefine the problem. When problem-solvers engage in these activities, not only are they redefining the problem, they are also engaging in imagining the possible. By questioning assumptions, the creator will be able to identify true restrictions and dismiss those that

do not truly apply, therefore increasing the potential and possibilities.

Importantly, problem redefinition is critically connected to possibilities. At the heart of problem redefinition is the recognition that the original definition of the problem was lacking or incomplete. The need to revise and redefine the problem drives the problem redefinition process. As such, the recognition of new possibilities is inherent in problem redefinition.

Prolepsis

Ignacio Brescó de Luna
Aalborg University, Aalborg, Denmark

Abstract

Prolepsis is an old and multifaceted term that could not be more significant in relation to the possible. From its original epicurean meaning, referring to the criteria of truth whereby we make judgments about the reality we perceive, prolepsis is generally associated with the notion of anticipation. In argumentation studies, prolepsis alludes to the anticipation of a possible counter-argument to one's discourse in order to answer it in advance, while in narratology it refers to the narrative figure of flash-forward or the anticipation of future events in a storyline. After providing some definitions of prolepsis, along with an historical contextualization of this term, this chapter delves into some current lines of research based on this concept with a particular focus on the sociocultural studies on developmental psychology and collective memory. The concluding discussion reflects on the theoretical significance of prolepsis in relation to the study of the possible in a technology-driven world, marked by acceleration of time and uncertainty.

Keywords

Prolepsis · Anticipation · Future orientation · Development · Sociocultural psychology · Collective memory

Introduction

Prolepsis is a term as old as it is multifaceted, as esoteric at first sight as it is inspiring and relevant in relation to the possible. Originally coined by Epicurus in the third century BC to refer to the sort of preconceptions through which we make judgments about the things we perceive (O'Keefe 2010), the notion of prolepsis has since been spilling out into different areas and taking on

different meanings. Generally speaking, the term prolepsis can be associated with the notion of "anticipation," whether in the Epicurean sense, as the criteria of truth against which we measure and judge our perceptions, as the rhetorical figure of foreseeing and forestalling objections against one's position by answering them in advance, or as the narrative anticipation whereby future events are textually related before their time. The notion of anticipation has also brought prolepsis into fields of study where time stands as a crucial element. Sociocultural approaches in developmental psychology have adopted the concept of prolepsis in order to examine how the anticipation of the child's future by the adult influences the upbringing. From a more sociogenetic perspective, anticipation of imagined futures is also taken into account when studying matters such as the reconstruction of collective past in national groups, the formation of social movements, or the role of technology, for example, through social media, in the way we experience the present as the object of a future memory (Currie 2007).

As the reader must have already anticipated, the meaning of prolepsis is inherently linked to other chapters contained in this volume. Prolepsis, as anticipation, implies a future orientation by going beyond the here-and-now. This includes phenomena ranging from argumentation, rhetoric and storytelling as well as issues around upbringing, learning, and memory that all encompass the very experience of time. Prolepsis also involves imagination about possible worlds or possible selves and thus the creation of imagined bridges toward what is yet to be developed. Last but not least, prolepsis cannot be understood without taking time into account; something crucial in development, be it ontogenetically, in relation to each individual's life course, or at a more sociogenetic level, in the formation of human groups.

This chapter will begin by providing some definitions of prolepsis¹ and contextualizing this term historically. It will continue by reviewing

¹Some meanings of prolepsis (viz., in grammar and botany) are not addressed in this chapter due to their irrelevance vis-à-vis the possible. For more information, see prolepsis (2007) in the Oxford English Dictionary.

some lines of research inspired by this term, giving preeminence to the sociocultural approach to it, especially in developmental psychology and memory studies. The chapter will conclude with a general reflection on the relevance of prolepsis vis-à-vis the study of the possible in a technology-driven world.

Some Definitions of Prolepsis

Etymologically, the term prolepsis stems from the Greek *prolambanein* which means “to take beforehand” (*pro* “before” plus *lambanein* or “to take”). *Prolepsis* is a key notion of Epicurean empiricist philosophy. As preconception or anticipation of the mind, it refers to empirically formed concepts derived from our previous perceptions accumulated in memory with which we become apt to make judgments about things. Two centuries after Epicurus, the Roman philosopher Cicero provided a Latin translation of prolepsis, as anticipation (*anticipationem*) and prenotation (*praenotio*), and defined this term as “a sort of preconceived mental picture of a thing, without which nothing can be understood or investigated or discussed” (p. 45). For their part, the Epicureans of the late Hellenistic and Roman period elaborated upon the original concept in different ways (Tsouna 2016). For instance, Lucretius, in his philosophical poem *De Rerum Natura*, translated prolepsis as *notitia* or *notities*, understood as preconception. Later on, another famous Epicurean, Diogenes Laertius, classified prolepsis – alongside sensations (*aistheseis*) and feelings (*pathe*) – as one of the criteria of truth, applying the term to the prototypes or exemplars (*týpos*) stored in our memory, as traces of our experience of the world, which we draw upon to make claims about it (Holmes 2005, p. 548). Along these lines, as Holmes (2005) points out, “Epicureans are often caught using prolepsis strategically to protect key claims from challenge, even when these extend, illegitimately it would seem, beyond the evidence available to direct perception” (p. 548).

This latter use of prolepsis brings us to the meaning of this term in rhetoric. In ancient Greece and Rome, prolepsis was employed in two

different ways by orators. One consisted of anticipating a reference prior to its actual introduction in a subsequent part of the speech, thus capturing listeners’ attention as they were challenged to infer the referent from the present or ensuing comments. As listed in the *Oxford English Dictionary*, this use of prolepsis can be defined as “the rhetorical figure in which a matter is stated in a brief summary manner before the particular details, aspects, etc., are set out” (Prolepsis 2007). The other rhetorical use of prolepsis, suggested at the end of the previous paragraph, is defined in the *Oxford English Dictionary* as: “The action of anticipating a possible objection or counter-argument in order to answer or discount it, or to deprive it of force” (Prolepsis 2007). This rhetorical figure, also known as *procatalepsis*, was particularly popular among Roman rhetoricians such as Quintilian who, in his *Institute of Oratory*, describes prolepsis as the “anticipation, by which I mean our answering of objections which we foresee” (Quintilian 1805, p. 161, cited in Besel 2012). This second use of prolepsis is still relevant in argumentation studies and is understood “as a means to position the speaker in a favourable way and to frame the issue in an acceptable way for the audience” (Xenitidou and Greco Morasso 2014, p. 104). Similar to what is known as a *disclaimer* in Discursive Psychology (see discourse), such an argumentative device is commonly used when people introduce a racist discourse by first denying being racist (“I am not a racist person, but. . .”). In this regard, rhetorical prolepsis aims to prevent the possible future it anticipates in the very act of anticipating it (Currie 2007), although, as some studies show, prolepsis miscalculation may lay the ground for the speaker’s opponents to raise objections not anticipated in the former’s discourse (Xenitidou and Greco Morasso 2014).

The notion of anticipation in prolepsis adopts another particular definition in narratology, also listed in the *Oxford English Dictionary*: “A prefiguring or foreshadowing of a future event in a narrative; the narration of an event at a point earlier than its chronological place in a story” (Prolepsis 2007). From this field, Genette (1980) defines prolepsis as “the narrative manoeuvre that

consists of narrating or evoking in advance an event that will take place in the future” (p. 40). So, contrary to analepsis or flashback – consisting of bringing the past into the present in the story – prolepsis or flash-forward is the anticipation of future events in a storyline before returning to the present of the tale to proceed with the sequence (Currie 2007, p. 29–31). One classic example can be found in the famous first lines of García Márquez’s book *One Hundred Years of Solitude*: “Many years later, as he faced the firing squad, Coronel Aureliano Buendía was to remember that distant afternoon when his father took him to discover ice” (1967/1970, p. 1). Bringing the future into the present – in this case, bringing the tragic outcome into the very beginning of the story – is a narrative mechanism for guiding the reader, since subsequent events in the plot acquire meaning and directionality vis-à-vis a future scenario already presented (for a cognitive approach to prolepsis in readers’ text processing, see Bridgeman 2005).

Drawing on this narrative meaning of prolepsis, some authors have reflected on how anticipation operates in life, what significance life events acquire when we look back upon them from an imagined possible future. Along these lines, Currie (2007) highlights how technology and the constant use of digital photography “installs in the present an anticipated future from which the present will be re-experienced as representation of the past” (p. 49). Thus, the growing tendency to stream our lives through social media would lead people to experience the present as an aesthetic commodity, as the object of a future memory. Currie (2007) connects this analysis to Derrida’s (1998) notion of *archive fever*, according to which moments exist only for the purposes of keeping a record. The very possibility of representing the past in the future makes recording devices, such as digital photography, play an important role in structuring the present in anticipation of its recollection. This idea is also linked to Derrida’s (1973) *logic of supplementarity*, which assumes “a kind of temporal loop by which things which happen later in a sequence are understood as the origins of things from which they apparently originate” (Currie 2007, p. 42). According to this logic,

instead of attributing a secondary role to the subsequent broadcasting of certain media events (say, a terrorist attack), such events would be originated by the very possibility of being broadcast later and remembered in the future. From this perspective, Currie (2007) concludes by comparing the narrative meaning of prolepsis with the *logic of supplementarity* that in both cases, the future is brought into the present in such a way that the anticipation of the former seems to cause the latter.

Anticipation appears to be at the core of the multiple meanings of prolepsis briefly described here. It is present in its original philosophical meaning, as an anticipation of the mind whereby we make judgments about things. As a rhetorical maneuver of anticipating future elements in speech or possible imagined objections to one’s position, the meaning of prolepsis is equally imbued with anticipation, although imagination and future orientation also come to the foreground as defining elements. These elements – inextricably related to time – appear to adhere to the subsequent meanings of prolepsis, whether as the anticipated future outcome of a storyline in narratology, or in the form of a projection, looking to an imagined possible future. In the latter case, the future-oriented aspect of prolepsis goes hand in hand with a kind of reversed causality whereby an imagined future appears to structure the present, making the latter anticipate its own past as the object of a future memory (Currie 2007). Using Aristotelian terms (see Aristotle), we can say that a final cause – a possible imagined future – becomes a significant one as it acquires pragmatic force in structuring the present. This logic is also central in various lines of research inspired by the notion of prolepsis, particularly in sociocultural approaches to developmental psychology and collective memory. In the following section, some research applications of prolepsis are briefly shown. In developmental studies, prolepsis is applied to child rearing, as well as to the study of children developing competencies through social interaction with adults. From a more sociogenetic perspective, prolepsis is also used to explore the development of social groups and the future-oriented

dimension of the collective past, as a particular case of constructive memory.

Research on Prolepsis

Sociocultural Approaches to Ontogenesis

Inspired by the works of Vygotsky, sociocultural approaches in psychology have been pursuing the reinstatement of a genuine developmental science focused on human experience in time. Along these lines, Michael Cole (1996) applies the concept of prolepsis in developmental psychology to the study of upbringing. According to Cole, adults interpret upbringing in terms of what they imagine or expect their child's future to be, the result being that parents' expectations mediate (see mediation) their actions during the upbringing, thus channeling the child's present toward the parents' imagined future. For instance, in relation to the parents' concept of, and expectations about, the child's gender, Cole (1996) points out:

Parents almost immediately start to talk about and to the child. The things they say arise in part from phylogenetically determined features (the anatomical differences between males and females) and in part from cultural features they have encountered in their own lives (including what they know to be typical of boys and girls). A typical comment about a newborn girl might be "I shall be worried to death when she's eighteen" or "She can't play rugby". (p. 184)

Parents' expectations about the child's possible future are, in turn, culturally mediated, since they are based on the parents' own past experience, including the way they were raised, as boys or girls. As can be noted, prolepsis operates as a future-oriented cultural mechanism whereby the imagined future of the child, based on the parents' past experiences, is brought into the present adults' handling of the baby. As Cole (1996) highlights, "only a culture-using human being can "reach into" the cultural past, project it into the future, and then "carry" that conceptual future "back" into the present to create the sociocultural environment of the newcomer" (p. 186).

Whereas in Cole (1996), prolepsis is understood as the child's present being structured in light of something that is not yet developed, other authors (Stone and Wertsch 1984) use prolepsis to analyze

the cycle of interactions whereby the child strives to infer adults' instructions in those joint activities whose goals are not yet understood by the former. This latter use of prolepsis is closer to one of its rhetorical meanings described in the previous section, the anticipation of a reference prior to its actual introduction later on in the speech, thus engaging the listeners by challenging them to infer the reference for themselves from the present or ensuing comments. According to Stone (1998), this is what adults unintentionally do when interacting with children and guiding them into the accomplishment of a joint task whose meaning is beyond the child's grasp. Just as audiences in ancient times were challenged to infer the meaning of a speech in advance, so the child is challenged to act in anticipation of fully comprehending the task and must develop an understanding from the actions or instructions in which he or she is led to engage (Stone 1998). From this point of view, *proleptic instruction* (Rommetveit 1979) is understood as the communicative process, wherein a child, in carrying out another's instructions, ends up developing a better understanding of both the ultimate goal of the task and why his or her behaviors contribute to it (Stone and Wertsch 1984). Here, we can once again see a kind of reversed causality in operation, for it is not the child's previous competence in a certain task that makes the performance of that task possible; rather, it is the child's initial performance – when interacting with the adult – that enables her or his competence to gradually develop.

Prolepsis, as an anticipated competence made possible through previous social interaction, can be linked to some important concepts in sociocultural developmental psychology. It is in line with Vygotsky's (1978) notion of *interiorization* or *ingrowth* and his law of cultural development, according to which every mental function appears twice, first inter-mentally, then intramentally. In Vygotsky's words, "an operation that initially represents an external activity is reconstructed and begins to occur internally" (p. 56). Likewise, it runs through the concept of Zone of Proximal Development (Vygotsky 1978), namely the distance between the child's capacity to accomplish a task independently and the level of potential development through the guidance of others. It

also relates to the metaphor of scaffolding referring to situations where a more capable other guides a child to accomplish a task while leading the latter to assume more responsibility over the activity in question (Stone 1998). This implies a transfer of task understanding resulting in a shift from other-regulation – through the adult’s instructions – toward a gradual self-regulation by the child in taking responsibility for the task and being able to solve it independently. This change from other-regulation to self-regulation, so important in socio-cultural developmental psychology, leads some authors to the terminological division of prolepsis into two types: *heteroprolepsis* and *autoprolepsis*. According to Meshcheryakov (2007), heteroprolepsis occurs whenever the adult, in interacting with the child, anticipates something that is yet to be developed. In a similar way to the process described above, when a mother addresses her toddler as a being capable of communicative activity, she is proleptically calling the child’s potential development into being by means of her speech and instructions. On the other hand, autoprolepsis implies a form of self-anticipation, such as when a child imagines him or herself in the role of a possible future self by playing adult roles (mother, teacher, older brother, etc.). According to Meshcheryakov (2007), “we can assume that in early ontogenesis there is a shift from heteroprolepsis to autoprolepsis” (p. 167).

Sociocultural Approaches to Sociogenesis

Heteroprolepsis and autoprolepsis, as theoretical tools to study development in ontogenesis, are also applied to study, from a sociogenetic perspective, the development of social groups. Taking a Marxist perspective (see Marxism) and in line with Vygotsky’s approach to development, De Smet (2012) departs from activity as a way to anticipate and develop new competences in the Egyptian workers’ movement in the face of the 2011 Revolution. In this context, autoprolepsis operates as a form of self-anticipation through action, enabling the workers’ movement to imagine a potential future moment in its struggle. In Smet’s (2012) own words:

Wildcat strikes and their illicit committees imagine trade unions; workers’ control over factories

establish their potential of running the economy without capitalists; and practices of participation, election, and discussion within the movement foreshadow forms of participative democracy. (p. 143)

If in autoprolepsis potential development is self-anticipated by the subject’s or group’s own actions, in heteroprolepsis, potential capacities are called into being by the action of another subject. In this case, the saliency of some actions carried out by a specific group of workers in Egypt (the Mahalla movement) became a form of heteroprolepsis for other organizations in the country to start similar struggles, using analogous actions, thus enabling initially scattered groups to gain consciousness of their shared class demands. In both cases, worker activism – originally born out of necessity – starts by producing social change; a change that then turns inward, producing changes inside the workers’ organization and making something not yet developed, such as the group’s political consciousness, possible.

Also from a sociogenetic view, prolepsis is applied to the study of how the collective past is remembered by groups. Departing from a constructive notion of memory, Brescó (2017, 2018) examines how the collective past is frequently reconstructed according to different imagined futures in order to foster current actions, thus guiding the present toward certain goals. Such a dynamic relationship between past, present, and future can be found in certain utopias, in most nation-building processes, as well as in nationalist movements seeking either independence or a nostalgic renewal of the past. Nationalist independence movements are paradigmatic cases of this, for it is the future independent state that leads the past to be nationally reconstructed, and rhetorically used, in order to justify such a political goal. In this way, the imagined future is presented as a natural consequence of the past, when in fact, the former has been brought into the present by a certain way of reconstructing the latter. Here, the weight shifts from the past to the future when it comes to explaining how memories are constantly constructed and reconstructed in the face of ever-changing collective goals and challenges. This, in turn, adds more complexity to the traditional linear concept of time, based on efficient causality, in

which events are inevitably pushed from the past into the future. According to this more-circular outlook, it is an imagined scenario that pulls the present toward the future through a certain way of reconstructing the collective past. Just like in Cole's (1996) upbringing example cited above, a final cause – the imagined future scenarios, be it of the child or the nation – becomes an efficient one as it acquires pragmatic force for mobilization, thus channeling current actions toward what is not yet present.

Prolepsis and the Possible in Today's Uncertain World

This chapter contains different meanings and applications of prolepsis. Mainly understood as a form of anticipation, it features examples of prolepsis operating at a microgenetic level in the way adults anticipate certain competences when interacting with children, at an ontogenetic level in how parents imagine the child's future life course, or on a more sociogenetic scale, when groups anticipate possible futures by engaging into action or by remembering the collective past. In all these cases, prolepsis implies bringing an imagined future into the present. As Currie (2007) points out:

...prolepsis produces the future in the act of envisaging it, so that the possible transforms itself into the actual. It does so in a range of modes and moods which can be placed somewhere on a scale between fear and hope. These two modes of [anticipation], fear and hope, clearly operate as much in the reading of a fictional narrative as they do in the everyday projections we make into the future, in our realisations and evasions of fearful outcomes, or our fulfilled and dashed hopes. (p. 44)

Prolepsis is positioned as a particularly relevant concept vis-à-vis political imagination in an accelerated and uncertain world (see uncertainty), where scientific and technological advances are shaping new ways of imagining the future in relation to the past and the present (see sociotechnical imaginaries). For example, since the advent of nuclear energy, and its military use in Hiroshima and Nagasaki, the visuals of the nuclear (the mushroom cloud, devastated cities, the radiation symbol, etc.) have been communicated worldwide. In so doing, they have

become a set of iconic artifacts for remembering the past vis-à-vis potential futures that we would like to build or avoid as a human species. The future can thus be imagined as a placid continuation of the present, or even as a progressive improvement of it. It might also be imagined as a dystopia inching closer to the present – as environmentalists warn, or as something to be gained and fought for in order to leave behind a past of inequity and conflict. Conversely, the past can also be something not to be repeated in the future as in the case of the nuclear bomb – or, by contrast, something we long to recover in the future, such as a nostalgic view of an imagined unproblematic past. In sum, through prolepsis, we are able to imagine a possible future in light of our actions carried out in the present, as well as to imagine other possible present-day realities in light of future scenarios we both fear may happen or hope to make possible.

Abstract

This article presents a propulsion theory of creative contributions and discusses the reward system under which it operates. The theory argues that creative contributions are of three kinds – paradigm-preserving, paradigm-defying, and paradigm-integrating. Within each of these categories are various kinds of contributions that change a field in different degrees. For example, the most valued kind of creative contribution is typically a paradigm-preserving forward incrementation, which moves a field forward a bit and threatens almost no one. In contrast, a paradigm redirection attempts to move the field in a different direction, threatening the work and standing of many in a given field, who then resist the direction suggested by the contribution. Reward systems for different kinds of creative contributions can change with time and place. For example, until recently, replications were valued little and often were devalued. Today, at least in some scientific fields such as psychology, they are valued much more because of perception on the part of some scientists that many published findings have proved not to be replicable.

Keywords

Propulsion theory · Advance forward incrementation · Conceptual replication · Forward incrementation · Redefinition · Redirection · Reconstructive/regressive redirection · Reinitiation · Synthesis

When we talk about what is possible, we must think creatively, because we are talking about projecting from what we know to what we do not know and only can imagine. Creative thinking is thinking about what is possible and how it builds on and departs from what we already know and can do. But people vary in how creatively they can imagine future and alternate worlds of possibility.

Marie Curie, Charles Darwin, Pablo Picasso, James Baldwin, and Pyotr Tchaikovsky were all, in their own domains of work, much more creative than the overwhelming majority of their peers, past and present. But they were not only *more creative*; they also were *differently creative*. That is, they were creative in ways that differentiate them from you, us, and pretty much everyone else we are likely to know. Even if we create new things, we are unlikely to be remembered for that work hundreds of years after our death; and we likely will never quite figure out what we could have done that would have put ourselves in the stellar company of people like Shakespeare, Mozart, and other superstars of the creative universe.

What is it that distinguishes these superstars, aside from the fact that they are more creative than nearly everyone else? We argue that they are creative in different ways from the large majority of people. A propulsion theory of creative contributions helps explain how (Sternberg 1999; Sternberg et al. 2001, 2002; Sternberg and Kaufman 2012).

The Propulsion Theory of Creative Contributions: A Brief Recap

The propulsion theory of creative contributions holds that creativity can vary not only in level but also in kind. Different kinds of creativity serve different functions in the universe of creative contributions. These different kinds of creative contributions, in turn, can be viewed as being of three different kinds: paradigm-preserving, paradigm-defying, and paradigm-integrating. The eight kinds of creativity, in brief, are as follows.

Paradigm-Preserving Kinds of Creative Contributions

There are four kinds of paradigm-preserving creative contributions.

Conceptual replication. Conceptual replication involves repeating work that has been done in the past but with meaningful changes to examine the generalizability of the previous work. An example would be extending validation of an intelligence test from a North American sample to a South American or Asian sample of individuals. Examples of such conceptual replications can be found in cross-cultural validations of intelligence tests (see Sternberg 2004). Replications can be found in any domain, from visual art to medicine to business.

Redefinition. Redefinition involves seeing a new use for something old. For example, aspirin originally was used for pain but then was used well for preventing a repeat of a heart attack. In scientific research, a redefinition was using intelligence tests not only for their original purpose – to predict school achievement (Binet and Simon 1916) – but also to predict long-term health-related or economic outcomes (Deary et al. 2009). Many revivals/remakes of theatre productions, television shows, or films fall into this category.

Forward incrementation. Forward incrementation is probably the most commonly encountered kind of creativity. Forward incrementation represents the next, usually fairly minor step in a program of creative achievement. For example, it might represent the next study in a series of studies, where each study represents some kind of programmatic progression in a research program. Thus, an extension of an existing model of reasoning to new kinds of reasoning problems would represent a forward incrementation (Sternberg and Gardner 1983).

Advance forward incrementation. An advance forward incrementation is a large step forward in an existing program of work and thus may be seen as an extension of the usual

forward incrementation. It is included as a separate category because whereas a forward incrementation typically is well received, an advance forward incrementation usually is not – it represents a step too far for many people in the field of the contribution. It may take years for such a creation to be properly recognized. One example of advance forward incrementation would be the introduction of online courses in US higher education. Although institutions that adopted this approach decades ago were viewed with skepticism at the time, online education is now being embraced by many leading traditional institutions of higher education (Lederman and Lieberman 2019). Early adopters had a highly innovative idea that was initially not accepted by the mainstream, but it has become clear that they were actually ahead of the curve.

Paradigm-Defying Kinds of Creative Contributions

There are three kinds of paradigm-defying creative contributions:

Redirection. A redirection takes a field where it is and suggests that the field is going in the wrong direction and thus needs to go in a new direction. Expanded models of intelligence (e.g., Gardner 1983, 2011; Sternberg 1985, *in press*) suggesting that *g*-based accounts of intelligence are insufficient to account for the whole of the phenomenon would be examples of redirections.

Reconstructive/regressive redirection. A reconstructive/regressive redirection is a kind of redirection, except one that redirects a field from where it once has been rather than from where it currently is. In a reconstructive/regressive redirection, an individual suggests that a field needs to move in a new direction but taking off from where it was in the past rather than from where it is now. The idea is that, at some point, the field went in the wrong direction and now needs to take a step back and return to where it was so as to achieve a redirection. An example would be work of Drew Westen (e.g., 1998), which argues that when

many clinical researchers threw out the theorizing of Sigmund Freud, they threw out the baby with the bathwater and lost valuable insights that could have led the field forward. Many restaurants with a retro feeling in décor or recipes (but modern techniques and sensibilities) may fall into this category.

Reinitiation. In reinitiation, a creative individual essentially decides that a field not only needs to redirect itself but actually needs essentially to start over. Einstein, Picasso, and Darwin were reinitiators. Einstein proposed a wholly new kind of physics, Darwin a new view on how life evolves, and Picasso (as well as Braque) a wholly new kind of art. Chomsky (2015) similarly was a reinitiator in the field of linguistics.

Paradigm-Integrating Kinds of Creative Contributions

There is one kind of paradigm-integrating creative contributions:

Synthesis. A synthesis is a uniting of work from two or more disciplines or paradigms. The late Herbert Simon was a master synthesizer, often bringing together ideas from economics, business, artificial intelligence, and psychology. Simon's most famous book, *Administrative Behavior* (Simon 1997), represented such a masterful synthesis.

Relation of Kinds of Creativity to Amounts of Creativity

In general, paradigm-defying and paradigm-integrating kinds of creativity represent greater amounts of creativity than do paradigm-preserving kinds of creativity (see also Kuhn 2012). However, this relation does not necessarily hold. For example, an advance forward incrementation can be highly creative. Similarly, a paradigm shift may be novel but not particularly high in quality, thereby fulfilling in large degree only part of the definition of creativity (see Kaufman and Sternberg 2019). In any field, there are dead-end paradigm shifts that start to take hold and then prove to be short-lived. For example, the act frequency approach in personality (Buss and

Craik 1983) originally seemed to represent an exciting new approach. However, it faded rather quickly because so much of personality is not directly represented in behavior and any behavioral act can represent multiple causes in personality (i.e., Does someone hit people because he is aggressive or because he is bullied or because he lacks physical inhibition?).

The Reward Structure for Different Kinds of Creativity

When we initially wrote about the propulsion model (e.g., Sternberg et al. 2002), we believed that the reward structure was somewhat straightforward. In the short run, we believed, forward incrementation tends to be the most rewarded kind of creativity because it moves a field forward at the same time yet also does not threaten existing paradigms and vested interests. Most articles in journals are forward incrementations because reviewers have little to lose in terms of their own status in the field if the forward incrementations are produced. Most funded grant proposals are forward incrementations for much the same reason – reviewers can easily recognize the incremental contribution of the work without feeling threatened, and moreover, they can have some degree of confidence that the forward incrementation will be successful, at least in some degree. In our initial view, conceptual replications tended not to be as highly rewarded in the short term because their creative contributions are, on average, smaller than are those of forward incrementations. Advance forward incrementations and paradigm-defying kinds of creativity tend most to be rewarded in the long run because they are field-changing but are less likely to be rewarded in the short run because they may threaten so many people. Critics may realize that these contributions not only transform the field but also risk turning their own work into an obsolete irrelevancy.

Some paradigm-defying contributions take off for a while, and then there is some kind of regression to the mean of what people have been doing before. For example, Howard Gardner's (1983,

2011) theory of multiple intelligences initially generated a lot of excitement among educators because it seemed to point a way forward for dealing with children who had distinctive talents but who were not being recognized as "intelligent" by the educational system. But its educational reach today is probably somewhat lower than it was in the early years after the first volume was published (1983). First, the theory was hard to test empirically. Second, scientific empirical support for the theory was, at best, weak (Visser et al. 2006). Third, the continued pressure of the testing culture in schools did not allow for much departure from teaching that, in essence, taught to the tests.

A more common occurrence is that a paradigm at first is dumped on by colleagues and only slowly comes to either be viewed as a viable alternative to the initial paradigm or else crowds out the initial paradigm. For example, the cognitive approach to intelligence got off to a relatively slow start (e.g., Hunt et al. 1973; Hunt et al. 1975; Sternberg 1977) but greatly picked up when its focus turned to the importance of working memory for intelligence (Conway et al. 2003; Kyllonen and Christal 1990).

Changes in the Structure of the Reward System over Time

Several so-called componential models of creativity have held that the environment for the production and evaluation of ideas is extremely important in terms of the creativity that emerges from a given environment (e.g., Amabile 1996; Sternberg and Lubart 1995). In both Amabile's and Sternberg and Lubart's componential models, the environment can be determinative of whether creativity even occurs. That is, even if other components of creativity are present, such as high levels of intellectual abilities, openness to experience, intrinsic motivation, and what Sternberg (1997) has called a "legislative style" – a desire to create – in the absence of a supportive environment, creativity may not emerge. Others have made a similar point. For example, Florida (2019) has pointed to the importance of cities in the development of creativity, and Simonton

(1999) has shown that highly creative individuals are more likely to emerge from some historical periods than others. These inquiries are relevant to our present examination of the environmental reward structure surrounding the kinds of creativity specified in the propulsion model.

When we wrote our original articles, we viewed the environmental reward system for different kinds of creative contributions as rather time-honored. That is, we saw a fixed reward system that almost always rewarded certain kinds of creative contributions while ignoring or penalizing others, at least in the short term. During our careers, however, we have seen what we believe is a change in the reward system in a way that, unfortunately, risks penalizing more serious kinds of creativity and, for better or worse, may increasingly reward less creative work. At the same time, we also have observed increased rewards for higher levels of innovation in some fields, such as artificial intelligence.

Increased Reward for Replication

One change is in increased value of replications, whose value we perceive as having risen substantially. Earlier in our careers, it was extremely hard to get replications published, and they were typically only published if there were multiple instances of non-replication and the study being replicated was viewed by the field as extremely important. When they were published, it tended to be in less prestigious journals. Today, even the most prestigious journals (such as *Nature* and *Advances in Methods and Practices in Psychological Science*) are publishing (registered) replications. *Psychological Bulletin* will devote an entire section or issue to replication, as have other journals such as *Perspectives on Psychological Science*. The interest in replication stems, at least in part, from what some perceive as a replication crisis in the behavioral sciences (e.g., Lindsey 2015; Open Science Collaboration 2015; Pashler and Harris 2012). The goal of such replications is not to do minimally creative conceptual replications but rather to perform direct replications. If these studies are creative, it is only in a minimal way; they are actually intended to be as uncreative as possible – that is, the goal is to reproduce the

original conditions of the initial studies as exactly as possible. This new interest in direct replication opens up prestigious channels for publication of research intended to be uncreative, something of a novelty in the scientific literature. In the past, uncreative studies were relegated to the journals at low points on the totem pole, rather than being published in journals at the top of the totem pole.

There are many advantages of the publication of such direct replications. First, they help ensure that findings perceived by the field to be important are real. Second, they provide a warning to investigators who might seek to publish studies with flimsy sampling or data analyses that they need to be vigilant because they may open themselves to frontal assault if their findings do not replicate. Third, these studies send a more general message to the field that solid results are important – that science only can be built on a firm foundation. Fourth, such studies provide an outlet for scientists who believe that science has been guilty of Type I errors and who want to play a role in correcting such errors. Fifth, replications prevent a waste of resources and time by preventing new studies and programs of research from being rooted in deeply flawed initial research.

We would argue, however, that at the same time that there are advantages to the new system of soliciting registered replications, there also may be some drawbacks in terms of the creativity of scientific research (see, e.g., Kaufman and Glăveanu 2018). First, the publication of registered replications, and the sometimes extreme publicity surrounding them, may lead some investigators to fear doing innovative work that may yield unexpected findings. The anxiety surrounding massive registered replications and the possible consequences of an unreplicated finding may be more than some investigators are ready to tolerate. So those investigators may be more cautious, indeed too cautious, in their creative work for fear of being shot down in a very public way.

Second, the rise of the Internet and social media have resulted in a culture of online attack that may increase investigators' fears of not only having their work not replicated but, more importantly, seeing their careers derailed. Such derailments

already are happening as a result of failures to replicate (Dominus 2017). Attacks in recent times, perhaps as a result of social media, have become much more personal, and scientists who might be able to withstand professional attacks may feel that they do not want to deal with the personal nature of some contemporary attacks. It is important to note that only a very small minority of scientists in this movement engage in these attacks, but even a few people can have quite an outsized impact. In a sense, the vitriolic and sometimes poisonous atmosphere of modern politics may be seeping into scientific discussion boards.

Third, the promotion of direct replications may send a message that creativity is no longer paramount in science. Certainly, there are other crucial components to scientific advancement; it is legitimate to argue that truth is ultimately more important than originality (Nosek et al. 2012). At the same time, it may be unreasonable to expect results to generalize to all populations at all times. As cultural shifts occur over time, results may change, especially in social psychology. For example, any result dependent on attitudes toward women, minority groups, or people with disabilities almost certainly will change over time. Many studies measure abilities, but even the nature of people's abilities may change over time (Greenfield *in press*). Perhaps investigators need better to specify in their original articles just how much generalization one can expect from their results (Simons et al. 2017).

Finally, there is a risk that individuals who otherwise might have become scientists decide to pursue other professions because they perceive the current atmosphere as intimidating or even hostile and that some people already in the field will move on to other fields because they view the current state of the field as one that just is not to their liking.

Simonton (1997) has proposed a model of creative productivity suggesting that scientific output varies over the course of a scientific career, usually decreasing as time goes on. Productivity may decrease for any number of reasons – increased administrative demands, one's running lower on

ideas within one's paradigm or paradigms of work, physical degradation, or whatever. Because the hit rate – that is, the rate at which a scientist produces work that has a high impact on his or her field – stays about the same over the course of a career, if productivity declines, so will creative hits.

According to Simonton's model as well as according to the actual data, all scientists, even the best ones, have failed ventures. The ventures may be based on faulty ideas, or in the case of psychology, they may produce data that do not replicate well. In the past, scientific failures were viewed as fairly routine parts of the enterprise. In today's environment, it is not clear that this rather benign view continues to hold. Many scientists and others today view replication failures, in particular, as quite serious. Because the stakes are high for a replication failure, it is hard to see how scientists would not become more cautious – indeed, that is part of the goal of the replication movement – leading to lowered productivity and, according to Simonton's model, a decrease in the number of highly creative hits. The question the field then would have to face is whether this possible decrease in creative productivity due to greater caution on the part of creative scientists is worth the price.

Obviously, there are advantages and disadvantages to any developments in science. But the question always is, when new practices are introduced into science or anything else, do their costs outweigh their benefits? That is something as yet to be determined. We as authors do not know the answer, and we suspect others are waiting to find out as well.

Increased Reward for Advance Forward Incrementation and Reinitiation

While psychology has seen an increase in caution, some fields have been experiencing a real push for innovation. The field of higher education in the United States has been under increasing scrutiny, and leaders have begun to call for change (Cavanaugh 2018; Davidson 2017). Great expansions in online education, once viewed with

skepticism, are now being embraced by many traditional institutions of higher education (Lederman and Lieberman 2019). Other issues highlight the pressure for innovation in higher education, including the increasing skepticism about the value proposition in higher education and the need for more employees in technical fields that typically do not require a 4-year degree (Kreighbaum 2018). In recent years, doctoral programs have been under pressure to mentor their PhD students to be prepared for alternative academic careers. As numerous factors converge on institutions of higher education, it is clear that the field that once rewarded the status quo will now demand innovation.

The reward for innovation is also apparent in the realm of primary and secondary education. In the face of various criticisms of the American public school system, increasing numbers of parents are choosing to educate their children at home. This can be viewed as a reinitiation, rejecting public and private education in favor of a personalized approach to education that permits a great deal of freedom in educational structure and content. Evidence that this radical response is being rewarded includes the growing number of children being homeschooled, from 1.7% of the school-age population in 1999 to 3.4% in 2012 (Redford et al. 2017). Whereas this is not a large proportion of school-age children, the dissatisfaction with public education resonates among a much broader population of families. This suggests that this creative approach will continue to be rewarded, and we would expect increased growth in homeschool communities and possibly also corresponding changes in public education.

Conclusion

Creativity can only be recognized in context: a specific time and place, an idea proposed by a particular individual in a particular field. Some creative contributions help us view the familiar in a new light. Others nudge the field a step further along a given path. Yet other innovations reject

the familiar and abandon the path and can start an entirely new field. In this chapter, we have argued that yet another aspect of the context for creativity is variable: the rewards for creative work (see also Amabile 1996). We urge creativity researchers and creators to consider how the context and its rewards affect their work and still strive for innovation whenever possible.

Prospection

Roy F. Baumeister and Kayne Lim
University of Queensland, Brisbane, QLD,
Australia

Abstract

Prospection, also known as thinking about the future, is present uniquely in humans. Prospection allows us to simulate and predict future events, the emotions borne out of these events, plan for whether we want to head toward them or avoid them, and take appropriate actions to steer our future. In essence, prospection is a key part of what makes us human and is closely intertwined with the unlimited possibilities of the future.

Introduction

Prospection is the act of thinking about the future. The term was first coined by Gilbert and Wilson in 2007, in contrast to the term “retrospection,” which refers to thinking about the past. Many people think about the future; in fact, people tend to think about the future more than they think about the past (Baumeister et al. 2016). Examples of prospection can range from thinking about the options for dinner a person might have for the night, to contemplating the possibility of an afterlife, with the most common form of prospection being planning for the days, weeks, and months ahead. Furthermore, prospection assumes that the future is changeable rather than predetermined, as only with a matrix of possible, mutually exclusive outcomes can prospection bring about any meaningful change in behavior (Baumeister et al. 2018b).

People think more about the future, even though most of studying psychology has focused on the past. In natural science’s models of causality, the past causes the present which then causes the future, so studying the past would have been the most useful for identifying the causes of present behavior. However, as humans have the ability to use mental time travel to simulate future scenarios and contemplate their choices, thinking about the future is thus adaptive, and the usual models of causality do not capture the whole cognitive process (Seligman et al. 2013).

Biology of Prospection

In neuroimaging studies, task blocks are interlaced with rest blocks that serve as a control. During these rest blocks, when participants are not given any tasks, the area known as the default network would activate, named after the fact that this area (in the midline and lateral parietal lobes; Shulman et al. 1997) would be active when the participant was seemingly at rest, suggesting that this was the brain’s “rest” state (Raichle et al. 2001). Following further investigation, however, participants whose brains were in default mode were, in fact, doing something – they were found to be engaging in mental simulation (Buckner and Carroll 2007). Both prospection and episodic memory (transporting the self-back into past events) activated the default region of the brain, suggesting a shared neural infrastructure for both of these processes. The two are grouped together as mental time travel (MTT), termed as such due to the concept that the person would simulate events in the past (episodic memory) or in the future (prospection).

Episodic memory is often flawed. Memory is not like a USB disk where an image is burned permanently onto it and can be retrieved perfectly every time; rather, the brain stores the relevant information and reconstructs the memory every time it is retrieved, and during this process, the memory distorts. Memories change a little every time they are reconstructed (Tulving 2002). A possible reason for this flaw is the purpose of the default network in the first place. Rather than

evolving for the purpose of using episodic memory, it is likely that the evolution of the default network was to simulate and prospect (Schacter and Addis 2007). Indeed, the abilities for humans to use episodic memory may have developed as a “side effect” of this brain structure that evolved to prospect. Hence, episodic memory recall is flawed because retrieving memories was never the primary purpose of those brain structures. The ability to simulate multiple different possibilities, as in when humans prospect about the future, was the intended purpose, and this flexibility had the unfortunate side effect of corrupting the retrieval process of episodic memory.

A Uniquely Human Trait

In general, prospection in nonhuman animals is minimal or at best limited to learned expectancies extending just moments into the future. There may be a few exceptions (Clayton and Dickinson 1998; Roberts and Feeney 2009). Scrub jays, birds that cache food for future consumption, were argued to have “episodic-like” memory (Clayton and Dickinson 1998). Scrub jays preferred worms, which were quickly perishable, to peanuts, which could last longer. When allowed to forage for their food soon after caching, they searched in spots where the preferred worms were buried, but if they were allowed to forage only days after, they searched in spots where the still edible peanuts were and ignored the already rotten worms. The authors suggested that the jays were able to simulate that the worms had already rotted following the period of time that they were not allowed to retrieve their food, and hence demonstrated episodic memory. Suddendorf and Corballis (2007), while acknowledging that the scrub jays demonstrated memory of when the food was buried, disputed the conclusion that the scrub jays had episodic memory or were able to use MTT. The peanut-seeking behavior could be achieved with purely informational components, such as the time of burying and retrieval, the location of the food, as well as the instinctual knowledge that worms would rot after a period of time, without actually simulating and

anticipating the event of digging up worms that were rotten. At present, it seems that MTT and prospection are still mostly used by humans, bar very few examples in the animal kingdom. It is also noteworthy that scrub jays are genetically quite different from humans. Evidence for prospection in nonhuman apes is also limited, such as that some will occasionally take a tool from one location to another where it will be useful. An important limitation of even these findings is that the animal is in the same motivational state. That is, the hungry ape will take a stick along to dig for edible bugs at another locale. Humans may well be the only creatures who are able to imagine futures in which they will be in a different motivational/emotional state (such as saving money for the future, dieting, refraining from angry aggression or illicit sex based on anticipating that they will be sorry if they act on current impulses).

Of particular interest is evidence that only humans can mentally simulate the future as a “matrix of maybe,” that is, a set of alternative possibilities, only some of which will come true. Chimpanzees are our closest cousins in terms of biology and intelligence, but it seems that even they are unable to employ prospection to any meaningful extent. Redshaw and Suddendorf (2016) demonstrated this when they had chimpanzees and human children learn to catch a treat falling through an inverted Y-shaped tube, such that the treat could come out from one of two possible holes. Older human children (aged 4) immediately started covering both holes with each of their hands, ensuring that they got their treat every time. Younger children (aged 2) and chimps, however, kept choosing a single hole at a time, reducing their chances of getting the treat by half. Furthermore, in the event where some chimps managed to cover both holes, they reverted to using one hand afterward. This suggests that older human children are able to distinguish that there were two distinct outcomes by simulating the possibilities in the future and were able to act to maximize their reward using this simulation. Chimps, on the other hand, were unable to do so, instead only employing simple stimulus-response contingencies of sticking out

an arm to stand a chance of getting a treat. The discrepancy in behavior not only showed the intellectual requirements needed for prospection with only older children being able to employ it, but also demonstrated the adaptive utility of prospection – by anticipating multiple possibilities by simulating the future via MTT, older children were able to maximize their chances of success and, in this case, guarantee a treat every time. The ability to simulate future possibilities also creates a space for human creativity to operate in.

Affective Forecasting: The First Foray into Prospection

The term “prospection” was coined by Gilbert and Wilson (2007), in a paper examining affective forecasting, which refers to the expectation of emotional response to future events. People can “pre-feel” events that occur in the future by simulating these events, and the simulation produces shifts in their current emotional state. However, this process is flawed. Gilbert and Wilson posit that the accuracy of the “pre-feeling” is affected by the simulation of the event, as well as the contextual state that the person is currently in. If there are inaccuracies in the simulation, or if there are differences in the states in which the simulation and the actual event are perceived in, the “pre-feeling” will be inaccurate to a degree.

According to the authors, the inaccuracy can come about in four different ways. The simulation can be **unrepresentative** – an extreme example is used for the simulation, e.g., using the most unsavory oyster one has ever eaten as a basis for the experience of eating all future oysters (Morewedge et al. 2005). This skews the pre-felt disgust of having to eat an (arguably delicious) oyster in the future. The simulation can be **essentialized**, where only the most salient portions of future emotion are considered and supposedly irrelevant factors are dismissed, and the essentialization is more pronounced when the event is further in the future, with the result being a more polarized version of the actually felt emotion. For example, people often think that parenthood is all bliss, but fail to account for the lack of sleep, late

night awakenings and involuntary remodeling of property, and hence have an overly optimistic view of parenthood.

Next, the simulation can be **abbreviated**, meaning that the expected emotion only covers a short time frame, without accounting for hedonic adaptation; that is, that happiness returns to pre-event levels over time (Lykken and Tellegen 1996). Lottery winners are often overjoyed at the prospects of a sudden windfall (who would not?), but are later often plagued with problems like relatives asking for money and impulse spending. Along with hedonic adaptation, lottery winners generally do not remain happy for extended periods of time, but people still constantly overestimate the joys of winning the lottery (Brickman et al. 1978). Finally, the simulation can be **decontextualized**, where contextual factors are not considered. As an example, spaghetti for breakfast can be appealing to hungry people, while spaghetti for dinner can be unappealing to people who are full, even though spaghetti should usually be appealing for dinner and not for breakfast (Gilbert et al. 2002).

The above examples may seem to demonstrate that affective forecasting is a fundamentally flawed process and may even be counterproductive. After all, why bother pre-feeling the future if the simulation is inaccurate? To quote Gilbert and Wilson (2007), “Alas, actually perceiving a bear is a potentially expensive way to learn about its adaptive significance. . .” While the simulations may not be entirely accurate, they still are correctly predictive of the emotion felt in the future, and thus provide valuable information on the potential consequences of certain actions, guiding people to make (by and large) better decisions. Crucially, Gilbert and Wilson’s research into affective forecasting set the stage for further research into prospection, as it had established an umbrella term for thoughts about the future, which was not previously available.

Anticipated Emotion

It turns out that affective forecasting is important in prospection guiding human behavior, because

actual emotion rarely directly drives behavior, but anticipated emotion does (DeWall et al. 2016), and affective forecasting is a part of this process of anticipating future emotion. In a similar vein to affective forecasting, anticipated emotion is a process whereby people learn that certain actions produce certain emotions, and use these past emotions to guide future action (Baumeister et al. 2007), and evidence of this process has been increasingly found. For example, in research regarding relationship satisfaction, Baker et al. (2017) found that the driver behind current commitment was not current relationship satisfaction, but anticipated future satisfaction, suggesting that people were willing to commit to their relationship more if they expected satisfaction in the future, not in the present. For evidence of the importance of anticipated emotion in guiding choice, Damasio (1994) examined brain-injured patients with blocked emotional responses. These participants could generate possibilities for future events but critically were unable to choose among these options. While participants could prospect, their brains were physically unable to simulate the anticipated emotion associated with each option, and hence they were unable to make a decision about their course of action.

Sometimes people take actions that produce positive emotions in the near future but bring unpleasant ones later on. Indeed, the combination of short-term gain and long-term cost has been one of the most durable formulas for self-defeating behavior (Baumeister and Scher 1988). Smoking cigarettes, procrastination, and shy avoidance of social interaction are familiar examples. Indeed, people with self-destructive lifestyles may curtail thinking about the distant future so as to stay focused on the pleasures of the present. For example, addictive drug use cultivates immediate bliss at the expense of long-term damage to health, relationships, and well-being. In a well-known study by Petry et al. (1998), college students and heroin addicts were both instructed to complete a story about a man who work up and began thinking about the future. The students' stories extended 5 years into the future, in stark contrast to the addicts' 2 weeks (Petry et al. 1998). Similarly, in a task where

participants were asked to decide on a sum of money that they would get immediately to give up a larger sum of money in the future, smokers were willing to settle for less money in the present as compared to non-smokers and ex-smokers (Bickel et al. 1999). The smokers and heroin addicts were displaying a pattern of future discounting that suggested an avoidance of prospecting the anticipated outcomes of their current actions, enabling their self-destructive behavior to continue.

Optimism and Forecasting

Optimism and pessimism are, by definition, intimately concerned with thinking about the future. People who expect to succeed and thrive are optimists, while people who expect to fail and spiral are pessimists, the key being expectations about their futures. In general, optimists tend to have better life outcomes than pessimists in a number of areas. Optimists tend to be healthier (Peterson et al. 2012), with decreased likelihood of developing diseases such as stroke, depression, and cardiovascular disease, as compared to pessimists. Optimists also tend to have higher psychological well-being than pessimists, being less stressed, lonely, and depressed (Scheier and Carver 1992). Despite these findings, optimism or pessimism may be a side effect of circumstance rather than an innate trait, in that people in favorable circumstances generally feel that they have more control over their actions and are likely to proceed favorably in life, as compared to people in less fortunate straits (Scheier et al. 2001), and people who are in favorable circumstances generally end up with better life outcomes. As such, a direct causal relationship between optimism and better life outcomes cannot be readily established.

As in affective forecasting, people's expectations of their own futures are also flawed to an extent. Two well-known biases are the optimism bias and the planning fallacy. The optimism bias refers to a systematic belief that one is less likely than others to encounter unfortunate events, and this belief is pervasive across ages, culture, and gender (O'Sullivan 2015). The bias arises partly

as a result of the illusion of having more insight into oneself than others have about themselves, giving them a greater sense of control of future events than other people (Harris 1996). The illusory increase in control leads to an underestimation of the likelihood of negative events happening to themselves. For example, smokers who think they are taking adequate precautionary measures to avoid lung cancer are likely to ignore the fact that many other smokers are also taking these measures, and yet still fall prey to lung cancer (Shepperd et al. 2002), resulting in an underestimation of the possibility of themselves getting cancer, as they feel more in control. As a result of this bias, people think they are less likely to fall ill, be retrenched, or crash while driving, and thus are unlikely to pursue the best course of action; smokers are less likely to quit smoking, drivers are more likely to drive drunk after a night out, and randy teenagers are more likely to have unprotected sex (Weinstein and Klein 1996): “It won’t happen to me.”

The planning fallacy, on the other hand, refers to the tendency to be overly optimistic when evaluating the amount of time and resources needed to complete a specific project (Lovallo and Kahneman 2003). The fallacy arises for similar reasons as errors in affective forecasting: people rely only on the most optimistic version of their forecasted progress and discount the seemingly irrelevant factors that could possibly delay or thwart progress on the project (Buehler et al. 2002), which could include procrastination, technical issues, or even general world events, such as the ongoing Covid-19 pandemic. This phenomenon is widespread, and even when people are explicitly instructed to consider possible obstacles to finishing the project on time, the amount of time needed to complete the time is still underestimated by a fair amount (Buehler et al. 1994). The consequences of underestimating a project are obvious: people promise things that they cannot realistically deliver, and result in stress, substandard work, and possibly even financial consequences. As an extreme example, by 2014, the next-generation F-35 Lightning II jet aircraft was considered 7 years behind schedule, and a whopping USD\$163 billion over budget (Dursch

2014). As a result, there was considerable negative publicity about both the manufacturing company Lockheed Martin, as well as the Pentagon. Both the optimism bias and planning fallacy can be considered flaws of prospection, as they reduce the accuracy of the forecasts about the future and lead people to make suboptimal decisions.

However, forecasts about the future can be made more accurate. Phillip Tetlock and Barbara Mellers, along with their team of researchers, showed as clear evidence for this as possible within the social sciences (Tetlock et al. 2014). During their so-called Good Judgment Project (GJP), the team of researchers took part in a geopolitical forecasting tournament hosted by the Intelligence Advanced Research Projects Activity (IARPA), pitting themselves against four other university teams in a contest of accurate predictions about political and global events. They recruited a team of 2,800 volunteers, and over the course of the 2 years in the tournament, tested 3 intervention methods to improve prediction: training, teaming, and tracking. Over the 2 years, they found conclusive evidence that a 45-min probabilistic training package improved the understanding of probable future events and facilitated the generation of new possibilities, and this translated into an increase in accuracy for trainees, over participants with no training. Teams of participants were also more accurate than individual participants due to the sharing of information and hypotheses, despite some well-documented group phenomena that hampered group performance like groupthink or social loafing (Esser 1998; Latané et al. 1979). Finally, as the study was conducted over a 2-year period, participants who performed the best were grouped together as “superforecasters” in the second year, and this group of superforecasters outperformed even expert forecasters with access to classified information (Mellers et al. 2014). Through the results of this study, Mellers and her team demonstrated that an improvement in forecasting the future was possible with any of their three interventions, and they were so successful (to an advantage of over 70% against the competition; Tetlock et al. 2014) that IARPA called off the competition after the first 2 years. In their book about the GJP, Phillip

Tetlock and Dan Gardner (2015, p. 51) also noted that individuals who tended to perform the best were “open-minded, careful, curious, and—above all—self-critical,” with certain personality traits being correlated to more accurate prospection. The discovery of effective interventions for more accurate forecasting means prospection can be improved, and the biases mentioned above can be overcome given the right circumstances.

Planning and Pragmatic Prospection Theory

Recent thought-sampling data found that when people report thinking about the future during daily life, three-quarters of such thoughts involve planning (Baumeister et al. 2018a). Planning is a mental activity in which the person formulates a series of actions to reach a desired outcome (Sjåstad and Baumeister 2018). Proper planning has been linked to a host of benefits, enabling goal pursuit and keeping distraction at bay (Gollwitzer 1996), and therefore allows for positive outcomes, be it to obtain groceries the next day or lose weight over the next couple of months. One of the main forms of planning is implementation intentions, and take the form of if-then contingencies: “if I encounter scenario X, I will perform action Y” (Gollwitzer 1999). While appearing simple and straightforward, this form of planning is very effective. Students asked to come up with implementation intentions for starting an exercise actually did start exercising, compared to students who were simply motivated – they did not start exercising more (Milne et al. 2002) – and people went for their flu shot much more when they had made implementation intentions as compared to when simply given information about the clinic (Milkman et al. 2011).

Another form of planning is process simulations, during which a person thinks about achieving their goals and generates the sequence of steps they would have to take to reach those goals (Taylor et al. 1998). This type of planning is effective in improving performance too, as people anticipate the types of actions needed and possible obstacles to achieving their goal, providing an effective strategy to achieve their goal. Outcome

simulation, on the other hand, which involves just simulating already having completed the goal, is not effective in promoting meaningful action towards goal completion (Kappes and Oettingen 2011), as simply imagining goal completion may actually reduce motivation to achieve that goal instead, while not producing any actionable steps.

In a similar vein to William James’ assertion that thinking is for doing (Fiske 1992), Baumeister et al. proposed that thinking about the future is typically a preparation for future actions and choices, in what they named pragmatic prospection (Baumeister et al. 2016). In their theory of pragmatic prospection, they argue that prospection is a two-step process. First, one first visualizes a certain goal in an optimistic manner, and at the same time generates the anticipated positive emotion as a result of achieving said goal. Afterwards, in a turn towards realism, they then generate possible negative outcomes and obstacles that would prevent them from reaching that goal. Taken together, these two steps allow a person to visualize and plan a course of action to achieve desired outcomes, while accounting for possible obstacles.

The steps occur in this order as there is first a need to discern what is desired before exploring what is undesirable. Furthermore, as the first step alone would not be enough to spur meaningful action (Kappes and Oettingen 2011), the second step is necessary to ensure that the person takes appropriate action to reach those goals. Anticipated emotion plays a part in this second step as well, letting the planner know which situations could potentially be hampering goal pursuit and which actions to take to avoid them. Furthermore, plans that are meaningful to the planner are more effective than others at achieving the goals set out by the planner (Koestner et al. 2002), because plans made in relation to one’s personal values would be more easily adhered to: “I was the one who wanted to make this diet happen, because I wanted to become healthier.” Plans that use one’s own actions as a trigger for future action are also more effective in ensuring action, as people who are involved in the flow of events of their plan rather than going off propositional factors like clock time are more likely to feel happy in control

of their lives (Sellier and Avnet 2014), adding to meaningfulness' importance in prospection – “After brushing my teeth, I will go to sleep” is more effective than “At 11pm, I will go to sleep.”

It is worth noting here that the future is seen as a “matrix of maybe” by the prospector (Baumeister et al. 2018b). The term means that the future is not seen as predetermined – as a series of events sure to occur – but rather a series of time points where the prospector's actions would change the flow of events and therefore result in different outcomes. From the viewpoint of pragmatic prospection theory, the idea of pre-determinism is untenable, as if prospection were about predicting events that would happen for sure, planning in itself would be meaningless, as the actions taken would not alter the outcome of events. However, as people routinely still generate action plans for events that have yet to happen, a pre-deterministic outlook on the future can be dismissed. Combined with the evidence found for anticipated emotion guiding action and the proportion of future thoughts that involves planning, the notion that prospection in general is innately involved with action to ensure better future outcomes is well supported.

Abstract

This entry provides an overview of the field of psychopathology – including the theoretical and clinical *study* of an individual's abnormal psychological thoughts, feelings, and behaviors (symptoms) as well as the personal *expression* of such manifestations. The first section is a general discussion of the field of study, outlining the ongoing concerns for the limits of nomothetic vs expressive, idiographic psychopathologies. A contemporary history of the field is sketched revealing these conflicting approaches and the place of objectivity, subjectivity, and their resolution into simultaneous presence. Then the main theoretical constructs in this history which have risen to prominence are put forward as the structure of current

psychopathology. The entry concludes by arguing that the relevant constructs are found in both a foundational manner in Alfred Adler's Individual Psychology and therein they play a synthesizing function in the application of psychotherapy today.

Keywords

Abnormal psychology · Personality disorder · Neurosis · Psychosis

Definition

The traditional etymological structure of “psychopathology” offers an intriguing first sense of the word: psyche / pathos / ology → the mind's / suffering / under study conditions. The scholarly definition provided by a national psychological association, however, captures two central characteristics that will be covered in this entry:

1. The *scientific study* of mental disorders, including their theoretical underpinnings, etiology, progression, symptomatology, diagnosis, and treatment. This broad discipline draws on research from numerous areas. The term in this sense is sometimes used synonymously with abnormal psychology;
2. The *behavioral or cognitive manifestations* of such disorders. The term in this sense is sometimes considered synonymous with mental disorder itself (APA 2015, <https://dictionary.apa.org/psychopathology>, italics added).

Introduction to Current Psychopathology

Correctly implied in the brief definition above, psychopathology is an enormous field of research that assesses thoughts, feelings, emotions, personality, and experiences of individuals, groups, and communities in their abnormal manifestation. Concise categories, however, cannot capture the activity involved in attempting to understand and explain human beings – well or ill. While categorization of the abnormal is a well-acknowledged

phenomenon within the field of psychopathology, persistent efforts to delineate the meanings and objectives of psychopathology without seeing its relationship to mental health are difficult or impossible. To look at behavior and diagnose it as abnormal will have either an acknowledged or unacknowledged concept against which the abnormal is being measured. It is like trying to define one end of a continuum with no awareness of the other end. This problem pervades psychopathology even currently and will be traced through the field's development.

Contemporary psychiatric authors strive to make psychopathology both useful and precise by developing a consensus that promotes the essential functions of psychopathology. The number of functions vary in the literature but typically include at least four proposals for psychopathology's chief purposes: (1) it is descriptive, in that it attends to the phenomenological experience of the person suffering psychopathology; (2) it is clinical in its linking the phenomenological with the classification (nosology) of psychopathologic experience; (3) it is theoretical by stipulating the foundational causes (etiology) of the psychopathologic experience; and (4) it is structural in its efforts to expose the meaningful coherence of psychopathologic experience (e.g., Cutting 2012; Schultze-Lutter et al. 2018; Stanghellini 2009).

Taken together, these specific functions of psychopathology give some breathing space to the main definition's focus on psychopathology as *scientific study* and *behavioral or cognitive manifestations*. The study of psychopathology includes explanatory aspects such as nosology and etiology and the behavioral manifestations themselves involve understanding aspects such as empathic observation of the suffering individual and concern for the meaning of the suffering for that individual. Studying the manifestations and observing them within living beings can unearth connections between and among (1) experiences, (2) categorizations, (3) causal foundations, and (4) meanings of psychopathology – all of which aim at healing the sufferer. In this way, we can say the study and observation of

psychopathology generates the possibility of psychotherapy.

This healing possibility, as will be shown below, is implied all along the development of the discipline: from the coining of the term “psychopathology” (Emminghaus 1878), through that term being first comprehensively organized as human maladaptation (Janet 1938), and its direct appeal at understanding along phenomenological lines (Jaspers 1913). Yet, throughout its history, the study and observation approaches have clashed with the experiences of the suffering individual. That is to say, the sufferer has to some degree been neglected in studying the suffering. Up until the present discussion, the “newer and better” nosology attempts have objectively suffered from both reliability and validity issues (Kotov et al. 2018; Ross and Margolis 2019). Subjectively they have been distrusted by the lay public for overlooking the human person for whom they purport to be concerned (Davis 1997; Spiegel 2005).

Study approaches can consider both etiology (source of the psychopathology) and pathogenesis (development of the psychopathology), but when such models are applied wholesale to the workings of the mind, they lead to manageable-enough general classifications of symptoms, but when considering individual, unique human beings normal and abnormal are hard to determine. That is, when the human subject is conceived within a narrow, causal model for diagnosing illness, the model pays little attention to the phenomenology (subjectivity) and teleology (purpose) of the psychopathological experience (see Andreasen 2006). The treatment of *mental* abnormalities as diagnosable via a medical model that treats *physical* illnesses has given rise to an ongoing “critique of psychopathology” (Cutting 2012). In his own thoroughgoing critique, Cutting sees philosophical consideration as *sine qua non* for understanding the suffering individual which for him already involves functional (psychological) and organic (neuropsychological) analyses.

Schultze-Lutter and her colleagues (2018) concur, while expanding considerably the differentiated psychopathology approaches needing to cooperate on “equal footing” if science is “to

succeed in understanding the underpinnings and mechanisms of mental disorders.” They emphasize not only psychiatry, psychology, neuroscience, and philosophy, but genetics, epidemiology, computer science, and mathematics as well (p. 4), concluding that “contemporary research and clinic in psychiatry do not need less but rather more differentiated psychopathologic approaches in order to develop approaches that integrate professional knowledge and patients’ self-experience” (p. 5).

So, the critical approach to psychopathology prevalent today reveals an interdisciplinary perspective making it far more compatible with the “both/and” orientation of possibility studies. As this article unfolds, it includes appreciation of both the study approach *as well as* openness to observing the experience of suffering individuals. It attends to etiology but re-emphasizes the utility and benefit of teleology; it recognizes salient pathogeneticists but underscores phenomenological experience and the importance of the individual sufferer.

Following from the definition of psychopathology, both the study of psychopathology for classification purposes and observing and empathizing with the suffering individual are now addressed. The overview of classification concerns is interwoven with the growing possibilities for practical understanding of mental suffering as they emerged from the early frustration of how to apply early psychopathological knowledge to healing endeavors.

Contemporary History of Psychopathology

Psychogenesis vs Phenomenology

Before large organizations began sharing information and gathering it into classification systems, came the initial attempts to explain what was entailed in psychopathic behavior, what separated it from that of everyday lives, and notably, what might be done about it. The first professionally organized attempts at encompassing anomalous behavior was made by the World Health Organization (WHO) at the turn of the 19th to

the twentieth century. In 1900 it first developed a taxonomy of illness and causes of death (Zavoronkov and Bhullar 2015). It was nearly a half century later in 1948 that WHO offered its first definition of health (Huber et al. 2011) – which was revised in 1984 (*World Health Organization (WHO) Definition Of Health – Public Health*). One hundred and twenty years after its inception, WHO is currently developing the 11th edition of its International Classification of Diseases (ICD-11). Notably, the ICD-10 already includes 11 categories into which 200+ distinct mental disorders, psychopathologies, are classified.

At the same time as and alongside classification efforts by the WHO, an attempt was developed for explaining psychopathological behavior with the aim to cure it. In 1902, the budding psychotherapeutic discipline of psychoanalysis came into existence under the guidance of **Sigmund Freud** [1856–1939]. He gathered with three colleagues to begin discussing a promising treatment for human mental suffering. Suffice it to say for now, that psychoanalysis initially distinguished the severity of mental disorders by a three-way designation: psychosis, neurosis, and perversion (Laplanche and Pontalis 1973). The initial prognoses of such disorders intended to delineate the curability of each and to identify which were amenable to therapeutic (psychoanalytic) intervention (Freud 1910/ 1957).

Psychopathology’s development eventually drew psychologists’ attention to differentiating between thoughts, attitudes, and actions that hurt oneself and those that hurt others. The former retained the moniker, psychopathology. **George Partridge** [1870–1953] worked to clarify the latter issue, harming others, as involving the greater community (Partridge 1930). This evolved as the originally separate discipline of sociopathy (Whitlock 1987).

These early-modern attempts to organize psychopathological disorders are part of a long continuum of human attempts to explain and understand human foible. In a broader context, psychology itself is a name given to the oldest attempts at grasping motivational forces of individuals along with differential aspects that separate humans from other animals. Egyptians,

Greeks, and later religions all sought to conceptualize the animating force of humanity. It is from them that designations of the terms “soul” or “psyche” gained philosophical currency. In this, psychology lagged behind the scientific curve in its development even until the eighteenth century, when the natural sciences blossomed. Early psychological understandings of the person, or of nature, were active among that century’s philosophers, among whom **Immanuel Kant** [1724–1804] was exemplary. His was among the early, grand attempts at understanding human motivation. With the influence of his *Critique of Pure Reason* (1781), psychology would ultimately be considered a scientific undertaking at the close of the eighteenth and beginning of the nineteenth centuries. This was a long and arduous road toward scientific acceptability that would finally be acknowledged with the 1890 publication of *Principles of Psychology* by **William James** [1842–1910].

That philosophy first came in the form of the materialistic philosophy of the time, which insisted that everything could be explained by biochemical processes. The brain was considered something of a modified mechanical organ – not unlike the eye, with its particular functions characterized accordingly. So, the original aim of a scientific psychology came to be the explanation of all behavior by mechanical principles. While of great interest to the growing scientific community, an *explanatory* approach did little to help *understand* either healthy or pathological mental life. These two perspectives would struggle with one another throughout the history of psychology.

Objectivity of Scientific Psychopathology

In the early 1800s, as natural science took center stage among intellects of the day and psychology was drafted into a scientific niche, treatment of psychopathological patients was consigned to institutions. Scientific growth of psychology notwithstanding, humane treatment of the individual sufferer would begin in 1793 when **Philippe Pinel** [1745–1826] was able to enact human reforms for his patients at the Salpêtrière and elsewhere in France (Elkes and Thorpe 1967). Certainly, science was making advances on many fronts.

Biochemistry could well explain individual activities such as enzyme activity and metabolism yet could not explain the maintenance of integrity – that the whole *precedes* its parts. Organisms, it seemed, were a unity whose parts are subordinated to the laws of indwelling purposiveness (Wexberg 1929). For the first time, alongside the etiological (cause-effect) approach, the teleological view (goal-orientation) was reintroduced. Purely mechanistic explanations, while still working somewhat in biology, were not only faltering there but no were no longer sufficient in psychology.

It was **Gustav Fechner** [1801–1887] who first developed a physiology of the senses. His approach was to develop divisions of psychic mechanisms into a catalogue of physio-psychology, namely, sensations, imaginations, feelings-emotions, will-desires, and so on. This was a revolutionary approach to the brain, yet try as they might, scientific attempts to apply this information to the complex behaviors of the mentally ill were failures.

It seemed that Fechner and his disciples could not satisfactorily explain subjective aspects of the individual. His physio-psychology (Fechner 1869/1966) was primarily speculative and remained sterile regarding classification of mental phenomena that helped deal with psychopathological behavior. As important as his Weber-Fechner law was (the observation that just-noticeable differences between two phenomena is in constant proportion of the original stimulus),¹ it had little practical utility for teachers and physicians who needed practical application of psychological information. Further, anecdotal efforts at understanding human nature were attempted, but the available intuitive understanding of human behavior could not produce replicable insight. Some level of organized scientific method was needed, and the scientific, mechanistic *explanations* of physio-psychology were proving unsuccessful. The sought-after

¹ More formally stated by Fancher 1996, that the stimulus must increase geometrically if the intensity of a sensation is to increase arithmetically.

fully-psychological *understanding* of human behavior was yet to be formulated.

Subjectivity of Scientific Psychopathology

As medical treatment grew in importance, however, so did issues of mental pathology and the stimulus to understand behavior was to come from this newer focus on psychopathology. A small but determined number of researchers produced a shift away from physio-psychology and toward fully psychological explanations for the psychological problems. **Jean-Martin Charcot** [1825–1893] was experimenting with hypnosis as it related to hysteria – which was still considered a brain phenomenon. At the same time, **Hippolyte Bernheim**'s [1840–1919] use of “suggestion” – controversial as it was (see Ellenberger 1970) – posited the first recognized *psychological*, non-material motivation for behavior.

Having been a university assistant for **Carl Gerhardt** [1833–1902], an early leader in pediatrics, **Hermann Emminghaus** [1845–1904] is responsible for using the term “psychopathology” probably for the first time in his publication of *General Psychopathology as an Introduction to the Study of Mental Disorders* (1878). **Emil Kraepelin** [1856–1926] filled the chair of psychiatry that Emminghaus vacated in 1886 and devoted himself to revising the psychopathology classification system current in his day. Kraepelin focused not just on major psychopathological symptoms but to the patterns of symptoms (syndromes). Both Emminghaus and **Pierre Janet** [1859–1947] broke new territory in understanding developmental aspects of psychopathology. In assembling the first comprehensive explanation of psychopathological behavior (see Ellenberger 1970, pp. 386–394), Janet advanced the first therapeutically workable psychopathology theory. He observed individuals who experienced “splitting of the personality” (dissociation) that he believed was caused by dynamic emotional excitation. He described this as “psychic automatism” – acts carried out mechanically without awareness. He described it as if the suffering individual were experiencing two souls living in a single body. Thus, he formulated the system in

which an “unconscious” state was opposed to a “conscious” state.

Given Emminghaus' coining of the term in 1887, broad use of the term, “psychopathology” is most frequently attributed to Karl Jaspers and his 1913 publication of *General Psychopathology. A guide for students, physicians, and psychologists*. It was his insistence that suffering individuals be attended to especially in their self-expression of psychopathological experience. “Since we never can perceive the psychic experience of the other in any direct fashion, there has to be an act of empathy. Our chief help in all this comes from the patients' own self-description” (Jaspers 1913/1997, p. 56). At this point in its development, the cause for pathological mental phenomena was no longer seen as related solely to brain mechanics. Rather psychologists were dealing with an “unconscious” which eluded mathematical or chemical proofs. It could best be understood via professional interpretation. Thus, the hypothesis of dissociation between conscious and unconscious grew in favor and displaced consciousness as the primary seat of human behavior.

Wilhelm Dilthey [1833–1911], although considered to be an empiricist by many, brought out the importance of a first-person oriented “understanding psychology.” Within the movement to develop a working psychopathology model, his approach opposed the prevalent third-person oriented “explaining psychology” which intended primarily to make the psychopathological conditions graspable and able to be shared and discussed objectively among concerned professionals. Dilthey's intentions were broader – he aimed to make the findings of mental aberrations understood from the perspective of the clients. Thus, helping professionals could focus on the individual's specific suffering. This was specifically what the physiological, explanatory psychology had not been able to accomplish.

Dilthey represented the shift from solely objective data to a conceptualizing which included phenomenological data. Rather than the once prevailing physiology's focus on only objective material, now subjective experience was cautiously admitted. Knowing that stand-alone

physiology had not worked and that a practical/usable psychology was needed, scientific exactitude, explanatory psychology, was by-and-large relinquished.

A culmination of understanding psychology was represented by **Edmund Husserl** [1859–1938] and his phenomenological approach. His “essential immanence” emphasized the indispensable unity and totality of immediate experience for understanding psychopathology. The consequence being that Fechner’s older efforts at cataloguing experiences appeared as artificial divisions.

Also at that time, biological science was evolving away from materialism as the pure physiology model of nineteenth century. So, while psychology’s original aim was to explain all mental activity by mechanical principles – with its failure on the physiological level – biochemistry as the familiar partner of mechanistic physiology began pointing in another, relativistic-biologic direction. Escaping this irrelevance, biochemistry better and better differentiated living from dead matter and, as a result, scientific interest turned to investigating living material. These investigations produced questions more fundamental to human life; those about organic material and about its biological phenomena, for example the process of regeneration in nature (e.g., tapeworm survival after vivisection) and the healing process in general. What grew to be a revolution in biology joined phenomenology in conceptualizing organisms as unities. As Smuts (1926) had conjectured philosophically and Goldstein (1934/1963) contended neurologically, maintenance of the integrity of the whole cannot be deduced biochemically. Each tissue and every organ seem to follow a law of the total organism.

At this point in psychopathology’s development the default for understanding maladaptive mental symptoms was no longer physiopsychological à la Fechner and other like-minded objectivists. Rather than brain malfunction, it was conjectured mental symptomology that might have its own meaning and purpose – at least to that organism. Psychopathologists were drawn to inquire under what circumstance maladaptive symptoms make sense. Taking a lead from the

newly invigorated biological sciences by speaking of “organism unity,” psychopathologists began to conjecture about unity within the personality. Still, “dissociative states” (Janet) and “psychic conflicts” (Freud) remained inexplicable and stood as a seeming contradiction of a unified personality. However, the more that was learned about *biochemistry*, the clearer it became that human behavior, normal and abnormal, would not be solved by finding a physicochemical formulae for organic activities.

Biochemistry, ultimately, could explain neither corporal nor mental vitality. If dreams and neurotic symptoms were not the result of biochemistry (i.e., imperfect brain functions), the question of “purpose” – something following an internal guide toward a discernable end – gained importance. Three influential psychologists more or less simultaneously offered their understanding of human purposive activity and its unique, phenomenological manifestation in individuals: from the depth psychological vantage point **Alfred Adler** [1870–1937], in his *Individual Psychology* (i.e., individual from German [and Latin] *individuum* implying an indivisible entity) posited an unconscious, fictional goal as the unifying element (Adler 1912/2002); from the individualistic developmental perspective **Wilhelm Stern** [1871–1938], within his *Personalistic Psychology* (Stern 1938) posited that the teleological nature of the individual accounted for the individual’s differences from other individuals; and **Kurt Goldstein** [1878–1965], from a psychopathological emphasis via his comprehensive, systems focus on “the organism” (Goldstein 1934/1963) illustrated the purposiveness of behavior as individual organisms striving toward actualization of the organism’s nature.

Objectivity vs Subjectivity in Scientific Psychopathology

Yet, the general acceptance of the phenomenological would occur only after struggling with and digesting such subjective phenomena as “dissociations” and “psychic conflicts.” The upshot of greater attention to such occurrences, however, did not immediately increase a search for understanding. Instead, it seemed to reinvigorate the

explanatory impulse, for an objective psychological science. Early interaction of behavioral psychology, in the form of reflex theory, made its claim to objectivity by ignoring the subjective and claiming it simply did not exist. Enter **Ivan Pavlov** [1849–1936] and **Vladimir Bekhterev** [1857–1927], professional competitors on a theory of conditioned reflex, and **Edward Thorndike** [1874–1949] who adapted the reflex theorists' notions and principles to learning theory. Even the response notations among these major influencers (*P R* = *perception* followed by *reaction*; *S R* = *stimulus* followed by *response*) ignored the human, subjective factor (*S O R* = *stimulus* followed by **organism** followed by *response*).

John Watson [1878–1958] incorporated such themes into his broader development of behaviorism and a comparative method of applying to humans what had been applied to animals. The behaviorist researchers and theoreticians carried out classical observations and experiments with a pledge to ignore or deny the subjective side of the results. This drive for objectified psychology and its therapeutic application culminated in **Burrhus Frederic Skinner** [1904–1990] and the behavior modification phenomenon. To provide ascendancy to an objective psychology, behavior modification asserted objective reasons for subjective phenomena it tracked, largely explaining such phenomena as self-deception (Skinner 1948, 1971). The effort held sway in psychology and psychopathology for several decades, but also provoked resistance that set a perpetual stage for a new subjective approach to psychology.

By his own standards, if not by those of behaviorism, Sigmund Freud also lent a hand of sorts to the quest for an objective psychology. He came to explain subjective behavior by developing several of what he considered “objective criteria” among his psychoanalytic concepts. He reworked Janet's dissociation of personality to be understood as the expression of the personality within that individual's conscious and unconscious systems (Wexberg 1929). This system freed Freud to focus more on the content of therapeutic observations, rather than gathering the content together in

categorical forms. By seeking causes within the *unconscious* content (patients' expressions), he believed he had established laws of explaining how abnormal outward, *conscious* conduct derived from *unconscious* activity of the mind.

In this sense, for the first time, a framework of psychopathology (*qua* psychoanalysis) was able to provide psychologically determined explanations for psychological occurrences. For example, “slips of the tongue” (a categorical form of psychic activity) were no longer explained by brain fatigue but were seen as linked to painful or unpleasant memories (the content of specific psychic activity). Freud believed he had found the bridge between subjective and objective psychology. He likely maintained this belief even as his later writings became more speculative and narrative – exemplified by his *Moses and Monotheism* (Freud 1964/1939). Therefore, it was only in the last decade of the nineteenth and dawning of the twentieth centuries that wholly psychological interventions, rather than physiological interpolations, were applied to dealing therapeutically with psychopathological behavior (Ellenberger 1970).

Thus, the nucleus of the dynamic individual was found in psychological movement which could produce mental activity to accomplish some purpose of the individual. This is the undisputed, noncontroversial contribution of Freud – despite many controversial positions he took on the etiology of psychopathological behavior over his long career of developing psychoanalysis (Sulloway 1979). As the subjective-objective groundwork took root, the first half of the twentieth century gave rise to the flourishing of three grand theories of psychopathology and psychotherapy: Psychoanalysis (Freud); Individual Psychology (Adler) and Analytic Psychology (**Carl Gustav Jung** [1875–1961]). All of these stayed intact and operative despite technological advances (Munroe 1955), an onslaught against phenomenology initiated by behaviorism, the rise of evidence-based medical and psychological standards of practice, as well as the contemporary burgeoning of neurobiology and neuropsychology following “the decade of the brain” (Jones and Mendell 1999).

Summary of the History of Psychopathology

Once the long wait for applied, effective psychologically pertinent interventions was ended, the would-be practitioners – physicians, clergy, educators, and other professional helpers – had at their disposal an approach to relieving the suffering shaped by psychopathological thoughts, feelings, and behavior. The long wait involved its own dynamics, fostering the evolution of a puzzling number of old and new psychopathological anomalies and the ability to address current issues (e.g., “war neurosis”) in new ways. It was not just the therapeutic techniques that changed, but the nomenclature surrounding such maladies. Dementia praecox, neurasthenia, hysteria, and the like all developed more specificity as the therapeutic interventions (medicinal and interpersonal) were found incrementally more effective.

By mid-twentieth century the booming psychotherapeutic response linked to the improvement of psychopathology saw the rise of other theories (e.g., humanism, cognitive-behavioral therapy) and still later, over 200 separate approaches to treat the most frequently occurring maladies of the given decade. Remarkably few of the theories and techniques developed their own expansive theories about the nature of the human being. What **anthropologies** existed – Freud’s psycho-sexual approach, Adler’s psycho-social approach, and Jung’s psycho-spiritual approach – addressed the most varied human characteristics, articulate human development over the evolution of the species, and could be applied with the intention of healing the widest variety of maladaptive behavior encountered today. Each of the 200+ newer approaches rely on one or the other of the three foundational psychopathological-psychotherapeutic models for their basic outlook on which is constructed the new, specific technique addressing the problems at hand (see Ehrenwald 1976).

Questions arise about the actual theoretical characteristics of today’s therapy models and whether they utilize anthropologies that are a combination of the grand three or are otherwise constituted. This is a complex enquiry that touches on the entry’s opening concern about *scientific study* and *behavioral or cognitive*

manifestations. Still, the most important issue for the field of possibility studies – shared by the major critiques of the psychodynamic approaches (Munroe 1955; Glover 1950; Holt 1989; Jacoby 1975) – is the ability of any theory to synthesize a vast amount of current scholarship about the nature of psychopathology, to provide a coherent understanding of it, while maintaining an eye toward individual healing. This concern is addressed in the following section.

Theoretical Constructs of Current Psychopathology

What then are the philosophical/theoretical characteristics that form a basis of existing psychopathology and psychotherapy? What can be gleaned from the previous perusal of history? There are at least four broad characteristics that prevail today and have been part of the development of psychopathology since Emminghaus’, Jaspers’, and Janet’s insisting that the experience of the suffering individual be the focus of any system that aims to explain *and* understand such mental suffering. Alongside these characteristics – phenomenology, holism, teleology, and social embeddedness – there is a striking absence (avoidance?) of what is meant by mental health. The common characteristics will be described here before offering evidence of their ubiquity in today’s therapeutic milieu which by-and-large, despite current psychopathology practices, subscribes to a model of wellness in providing psychotherapy.

Phenomenology has been brought forward as a necessary condition for a valid psychopathology throughout this entry. Due primarily to the influence of Karl Jaspers, psychopathology and psychotherapy today focus on the structures of individual experience, or consciousness – both in its aberration and its healing. Literally, phenomenology concentrates on things as they appear in the patient’s experience and provides meaning to things within that experience. This definition alludes to other closely related psychopathological strata, such as the *subjective* nature of one’s own mental activity giving rise to an individual experience rather than one that is shared or

communal, with little adherence to or awareness of an external, objective truth; an *idiographic approach* to life which gives credence first to the subjective nature of uniqueness over and against a generalizable outlook being considered preeminent; and an *existential* starting point of the experience, viewing the human subject not merely as thinking, but as a living (thinking, feeling, and acting) and vulnerable human individual.

Holistic experiencing of reality is another characteristic of current psychopathology/psychotherapy assessment and interaction. The originator of the concept of holism, Jan Smuts (1926) described the holistic perspective as life consisting of various interacting systems (e.g., physical, biological, social) each of which are whole and function unto themselves. Simultaneously they are also part of larger interactive wholes that join force to accomplish activities which the separate systems cannot attain.

Teleology, once disregarded as merely a philosophical perspective, is appreciated in psychopathology as an understanding of behavior as a function of its end, purpose, or goal. Within psychopathology it contrasts with etiology which references the psychogenetic cause of a malady. Teleology and etiology are understood today to be inseparable aspects of how a sickness starts and what course it naturally runs. The advantage of a psychological understanding of teleology is that it provides consideration of the cost–benefit ratio of so-called secondary outcomes that manifest in the psychopathologic experience. At the same time, the future orientation emphasizes the possibility for healing within that future – and so is coupled to issues of *wellness*.

Social embeddedness of individuals is being newly affirmed in neurological imaging, notwithstanding the subjective and individual *experience* of life. Now given credence in interpersonal neurobiology as the “mirror neuron” system is studied and understood, being wired for connection with others (Siegel 2020) helps grasp what is regularly manifested in family and community structures. Allusions have been made throughout history of the dignity of the human person in fellowship with others that it is not tenable to postulate society as if it confronts the individual. The individual *is* social

being; individual human life and species life are not different things (Adler 1994).

While these four characteristic ways for perceiving reality contrast mightily with the perceptions of the pathologically suffering individual, it is by utilizing such an outlook that the therapist or pathologist can locate the sufferer within coordinates that simultaneously provide a structure for the extent of the illness, conjecture about the perceptual model used by the patient, as well as offer a way back to relative health. The four characteristics represent a therapeutic confluence of healing factors that finally gained traction in the earlier history of psychopathology. And while the distinction between *categorizing* and *observing* became clear enough, the co-equal importance of each characteristic is only now being recognized, nearly a century after the impetus of therapeutic interventions for healing psychopathological conditions.

For much of the developmental history of psychopathology, describing and explaining the problem was seen as disconnected from the intention of understanding; objective observation was seen as superior to subjective experience, the former was considered a scientific necessity while the latter was often considered a scientific nicety. Freud became an unwitting bridge between the objective and subjective approaches to human well-being. He believed himself to be firmly on the side of objectivity. He was, by James’ (1907) formulation, “tough-minded,” an empiricist and materialistic psychologist. For MacKinnon and Maslow (1951), “Freud rested squarely on 19th century scientific theory in his reductionism, his tendency to analyze, to dissect, to dichotomize” (p. 642). He, nonetheless, set forward the conditions under which an understanding of the mind involved *more* than measurable conscious cognitive activity. This was the door through which it became possible to bypass physiology and to psychologically understand psychopathology.

Ironically, it was Adler, Freud’s first defecting colleague, whose temperament and theorizing was better prepared to embrace objective and subjective psychology simultaneously. His holistic “both/and” position better fit James’ formulation (1907) of the “tender-minded” psychologist

who was both idealistic and monistic in his outlook on an integrated reality. But defectors from Freud's school of psychoanalysis did not fare well—a story that takes up volumes of history and psychology texts starting with Freud (1914) himself.

The salient point here is that in the development of psychopathology, the only two individuals who developed grand anthropological and psychopathological theories that remain today – besides Freud himself – were his first two dissenters, Adler and Jung. Neither originally intended to modify psychoanalysis; both believed the depth perspective allowed for different conceptualizations of the psyche. Historically, each found their theories developing while collaborating with Freud, yet both had initiated their views separate from him (Ellenberger 1970): Jung in an esoteric direction, Adler in the direction of social psychology. The distinctions among the “triple star” of psychodynamic practitioners cannot be overstressed, but here the Ansbachers' (1964) helpful overview will suffice.

Regarding **Freud's** field of inquiry – the vast context from which he viewed psychopathological issues – was based in human physiology. From here, he looked “into” the individual and sought to grasp the function of instincts as an intrapsychic issue. **Adler**, by contrast, contextualized psychopathology from an organic perspective: the individual (indivisible, holistic) organism was a complete functioning whole whose unified functioning occurred within the larger “organic” setting of culture. This viewpoint assumed that transactions between and among the individuals would provide evidence of both individual and communal psychopathology. **Jung**, for his part, was interested in what he considered a vast spiritual context where symbolism – mental/spiritual and archeological – could point to connections among peoples, and perhaps yield evidence of collective psychopathology.

From **Freud's** physiological field of inquiry, conflict became his frame of reference. Whether great or modest, all is in conflict: the death instinct conflicts with the life instinct; the superego conflicts with society; and, most fundamentally, consciousness conflicts with unconsciousness. **Adler's** inquiry from within an organically

interconnected field made his frame of reference the problem of cooperation within the community – from social inclusion to social exclusion. **Jung's** intangible field of symbolism made his frame of reference similarly nonmaterial as he concerned himself with the impenetrable mysteries of life, the esoteric, and arcane.

Not surprisingly, the methodologies applied by the three facilitated their arrival at altogether disparate findings about the resolution of psychopathological issues. **Freud** emphasized that the conflictual human journey within society could be accomplished only by embracing the reality principle, a conscious containment of personal pleasures so that a modicum of harmony can rise among individuals and communities. **Adler** conjectured that the evolutionary impulse that brought the human organism together with others for protection and survival had progressed along a continuum starting from parent/child affection and extending to appreciation for and participation in community. He believed this feeling for community (*Gemeinschaftsgefühl*), wherein both the individual and the community find mutual benefit, needed developing in all individuals. **Jung** saw the way to stable mental health by means of the lifelong individuation process – a conscious effort of uniting the personal and collective unconscious to become aware of one's place in the largest context.

Adlerian Thought and Current Psychopathology

It may be clear from this comparison that in practical application the three systems are not equally parsimonious. Determining their application in the psychopathology sphere, Adler's was undoubtedly – and deceptively – simpler. Ignored or criticized for being simply ego psychology (Freud, 1914) it is, nonetheless, Adler's Individual Psychology which most expresses the outlook on psychopathology today with its phenomenological, teleologic, holistic, socially focused, wellness orientation. The largely unacknowledged infiltration of Adler's thought *into* current psychotherapy practices today has been outlined in the opening essays of Heinz and Rowena Ansbachers' three compilations of Adler's works

(1956, 1964, 1978).² They were not alone in their finding. Henri Ellenberger (1970), historian of psychiatry, contended, “It would not be easy to find another author from which so much has been borrowed from all sides without acknowledgment than Alfred Adler” (p. 645).

This not only pertains to current psychotherapeutics but was already underway upon the separation of Freud and Adler. As far back as 1917, when Adler’s opus magnum, *The Neurotic Character*, was translated into English the actual development of therapeutic interventions strongly favored Adler’s interpretation of psychopathology despite using Freud’s nomenclature in psychotherapy generally (see Shon & Mansager, 2019). And it was an early follower of Freud, Fritz Wittels (1939) who determined that the neo-Freudians could properly be called neo-Adlerians. Ansbacher and Ansbacher (1956) identified nine prominent neo-Freudians whose position could be described as “stressing social relations rather than biological factors, the self rather than the id and the superego, the striving for self-actualization rather than the sex instinct, and the present situation rather than early experiences” (p. 16).

While there is not much mention of Adler among the psychoanalytic community at present, when the object relations theory of personality (Fairbairn 1954; Kernberg 1995) largely displaced the latent sexuality focus within psychoanalysis with a relational emphasis, even psychoanalytic authors could recognize Adler’s social focus as an originating influence (see Borden 2015). Already in the 1960s, the humanistic psychology movement – as “third force” in psychology’s development after psychoanalysis and behaviorism – became increasingly influential. It was then that Adler’s understanding of human nature could be differentiated from the development of psychoanalysis (Maslow 1962) and be seen as a major influence on humanism itself. At the same time other theorists (see Rotter 1962) recognized Adler’s contribution and

summarized the obvious alignment of psychopathology and psychotherapy *away from* Freud and *toward* Adler’s understanding: away from explaining behavior based on instincts, and toward a stress on the necessity and benefits of communal interaction (social embeddedness); away from considering sexual drive as a primary human determinant, and toward a more organismic understanding of a future-oriented human being (holism and teleology); away from the view of the person as amoral and therapy as a zone of “value free neutrality,” and toward a view of the person as at least capable of being an autonomous moral agent and recognition of the tacit influence that values play in psychopathology assessment and psychotherapy (phenomenology and social responsibility). These shifts were strong and consistent enough to withstand applied scrutiny and criticism from the psychoanalytic community (Kernberg 2011), and reliably evident in the current psychotherapies that *The Journal of Individual Psychology (JIP)* regularly and effectively provided comparisons of psychopathology theory and clinical practice within its pages.

Beyond the proponents of object relations and self-psychology who emphasized the relational nature of humans (e.g., Kernberg, Kohut), and the humanistic psychologies who flourished in the presentation of growth potential (e.g., Rogers, Maslow), Heinz Ansbacher, an early editor of the *JIP*, and subsequent *JIP* authors have made evident the early and persistent connection of psychotherapeutic development with Individual Psychology:

Interpersonalists offered a primary alternative to the intrapersonal nature of psychoanalysis (e.g., Sullivan); feminists championed equality of sexes opposing Freud’s contention that anatomy is destiny (e.g., Horney); social psychologies emphasized the context of larger interactions as not solely contentious as Freud did (e.g., Fromm); existential psychologies re-presented the mode of being as the subjective and phenomenological aspect of human integrity (e.g., May, Yalom); family and systems approaches addressed holistically intertwined interactions and transactions (e.g., Satire, Manuchin); the cognitive behavioral approaches (Ellis, Beck) developed a plethora of techniques for restructuring one’s phenomenological, subjective outlook on reality (e.g., Ellis, Beck); constructivist theory has again brought forward the subjective impact in a wholly postmodern manner (e.g., Kelly, Berger, Luckmann);

²These texts, prior to the publishing of *The Collected Clinical Works of Alfred Adler* (2002–2006), were the most accessible means to Adler’s theory by English-speaking professionals.

somatosensory approaches restate the holistic connections of the human being and its social interactions (e.g., Lavigne); family constellations work with the positive-negative energy within systemic family bonds (e.g., Hellingner); emotion-focused therapy emphasizes the security of emotional bonding (e.g., Johnson); while polyvagal theory accentuates the social engagement system and the social embeddedness of the individual (e.g., Porges); and, interpersonal neurobiology presents social connections as hardwired into the human system (e.g., Siegel).

These instances of Adler's structural influence on both psychopathology and psychotherapy arguably have become most apparent within the Positive Psychology movement today and its developing impact on optimal health (Watts and Ergüner-Tekinalp 2017). Seligman and Csikszentmihalyi (2000) have inspired a commanding amount of quantitative and qualitative research which gives credence to its declaration of being the declared school which offers an alternative to the causal-medical model of psychopathology today (Kobau et al. 2011). Its own growing research findings have convincingly established that "negative" inquiry and approach to human behavior no longer have complete dominance within the field. This has been clarified in contemporary critiques so that the issue is less one of positive/negative and more of causal/teleological inquiry (Wright 2014; Lazarus 2003).

Foundational Strength of Adler's Individual Psychology

Hopefully, the main philosophical underpinnings that are found though this entry's previous history-taking and current manifestation of psychopathology are now clear. Questions that remain are less about how the four constructs are presented in various psychotherapeutic approaches – since they appear in all of them – than about the extent to which each one is exhibited in each therapeutic methodology. Especially regarding current psychotherapies, the issue of resolving suffering begs the question: Within the whole of any given approach (psychopathology or psychotherapy), in what combination ("quantity" or "ratio") do the constructs appear?

It is in answer to this pivotal question that Alfred Adler again comes to the fore; not because he was

the originator of any of these concepts or the first to include any one of them in his approach, but because his style of thinking – indeed his entire style of living (see Hoffman 1994), seamlessly intertwined these perceptive schemata into a unique vision and understanding of humanity.

Adler was not the only theoretician or practitioner to address issues of phenomenology. As we have seen, others thought along these lines as well. Adler was not the first or only physician to holistically conceptualize his patients' suffering. Characteristically, Adler acknowledged his debt to Jan Smuts for Smuts' original conceptualization of the term, but other of his contemporaries were thinking along these lines. Of course, the teleological perspective is at least as old as Aristotle (Johnson 2005), and Adler was among a group of physicians who took their cues from organic life which could be seen restoring itself to a seemingly "planned" end-state long before DNA was hypothesized. Finally, the most noticeable battle in the psychodynamic outlook had to do with social embeddedness: was personal psychopathology an inwardly oriented or an outwardly oriented event? Adler was not alone in this arena either, nor can he be seen solely as Freud's adversary. The individual for Adler did not represent a dualistic, potentially antagonistically dynamic being. Instead, the two orientations – inward and outward – existed together, influencing one another, one taking ascendance if needed depending on the circumstances.

Adler's contribution was this solid positioning in the liminal place despite the cognitive dissonance engendered; and it led quickly and effectively to his ostracization among the original psychoanalytic community. By occupying a position on both sides of a boundary, he enlivened perceptions of humankind. Here, the internal dynamic of the individual is set within socially embedded circumstances – with each boundary continually, and vigorously, influencing the other. This typical stance of his prevailed regarding pathological cause and effect as well. Both the starting point (cause), what Adler understood as the exogenous factor of a given psychopathology, and its ending point (effect) were relative to one another, to the individual and to the circumstance.

In practice, this relativity did not result in ambiguous diagnoses. Rather, it was comprehensively decisive for the phenomenal individual. This is precisely the benefit of Adler's synthesizing approach to the unique possibility in psychopathological expression. He insisted on a distinction between the *general* and the *specific* diagnoses.

The *general* diagnosis – which all nosology seeks to provide – focuses on categorical and systematic presentations of the symptomology. Current efforts to personalize such symptom-based nosology (Schultze-Lutter et al. 2018) remains bound in the general and cannot go directly in a healing direction. Only by including simultaneously the circumstances surrounding the individual, as well as the person's internal dynamic, can a *specific* diagnosis be rendered: a diagnosis which by its phenomenological focus, potentially reveals the unique healing procedure.

By its etiological orientation, the *general* diagnosis is not designed to heal but to provide the conditions under which the healing regimen can be determined and implemented. On the other hand, by its teleological orientation, the *specific* diagnosis focuses on the individual interacting with its environment (expansively understood), and presents the possible distortions of thinking, feeling, and interacting and suggests their purpose – all of which are included in the healing process.

In this context, teleology can be seen to have differentiated meanings regarding psychopathology. As “end” it can refer to the effect which follows a causal incident; and in this sense it is a *relative end*. Teleology can also reference the normal course an illness runs until it is finished, and death occurs, or health is restored as the *final end*. But from the phenomenological, holistic, teleologic, socially embedded perspective, it can also be the *intended end* which was conceived in some fashion from the outset. Such “intentionality” will have to be addressed below, but for now we have provided the warrant for Adler's Individual Psychology being considered as especially suited for presenting the contribution of possibility studies *visa vie* psychopathology. What is left is for the authors to highlight two of Adler's *clinical* concepts to demonstrate some positioning of the possible. This will be done by addressing how Adler's anthropology construed movement toward wellness within psychopathology.

Summary: Synthesizing Possibilities of Current Psychopathology

In this section, the traditional concentrations of psychopathology – both the assessment of thoughts, feelings, emotions, personality, as well as the resulting experiences – are introduced under Adler's construct of expressive, dynamic, psychological *movement* (Stein 2014; Stern 2010). Adler conceived of organic life generally as movement from a minus position (–) to a plus position (+), from a state of incompleteness to a striving for completion.

For Adler, our human experience of life, meaning the psychic life, flows from the organic life and the striving from minus to plus. He famously described this movement as striving from a felt inferiority to a fictional superiority. Both concepts of inferiority and superiority were generally neutral except in the valuation (feeling tone) of the individual. Thus, the movement toward superiority over challenges in life was frequently termed “mastery” or conquering the adversity. When one's striving movement aimed at becoming superior to another individual, however, it was usually termed “power over” the other. In this way the impetus to move, to strive, was *stimulated* by the sense of inferiority. This understanding of the innate power-distribution of humanity became a truncated cliché about Adler's method among detractors within the psychoanalytic schools (Jones 1955).

In fact, Adler's theory continued to develop after leaving Freud. It was likely due to his treating frontline soldiers during the First World War that Adler began to think of the direction of the impetus to overcome one's inferiority feelings. In the years just after the Great War, Adler posited an innate potential, the possibility, of a given direction being established for movement from the minus to the plus. He conceived this as one's relative interest in being socially embedded, or being *socially interested* in one's surroundings. For Adler (1918), a dual dynamic of motion and direction parsimoniously represented the basic human striving found in human interactions of all kinds. When the stimulated direction was toward, for, or with others Adler, from a utilitarian

viewpoint, identified such action on the useful, helpful, or contributing side of life – one had an adequate feeling for community (*Gemeinschaftsgefühl*). When the movement was away from, against, or left out others, he concluded they were useless to, unhelpful for, or detracting from the commonweal. This level of one's social interest was inadequate to sustain real benefit for the community or the existential wellbeing of the individual.

Such striving or movement was part of Adler's overall construction of a general diagnostic continuum along which *psychopathology* and *wellness* could be located. He did not describe the two as opposite one another, but in relationship by means of their force (derived from the depth of the inferiority feeling) and direction (relative amount of social interest). Socially interested striving accounted for cohesive communal living, while the striving that lacks social interest manifest as more self-bound and would be used when pitting one individual or group against the other. From this construction, psychopathologic expressions – whether activities, thoughts, or feelings – remain the focus. But, for Adler, wellness could for the first time be understood in terms beyond “that from which” pathology deviates.

From what has been explored here, *movement* and *social interest* have emerged as the synthesizing clinical constructs for the four salient characteristics of psychopathology – phenomenology, holism, teleology, and social embeddedness. Categorization of symptoms can be accomplished by conceptualizing the motion as “frozen,” but categorization cannot in itself offer a perception of the *living*, moving entity. Movement is phenomenologically personal and idiosyncratic, and its relationship to wellness embraces all aspects of life. Interacting waves of movement from others advance toward a goal as “forward” in the direction life takes – and where possibility lies. In order to see the movement within a frozen symptom, the phenomenal individual is considered as part of the holistic milieu in which the self-motivation to

escape feeling inferior (by striving for a goal of superiority) embeds the individual to some degree in relationship to others.

Equity · Social Justice · Institutions ·
Capitalism · Utopias

When radical critics of capitalism become desperate for empirical models that embody their aspirations, wishful thinking can triumph over sober assessments. The complementary danger is cynicism; there is great cachet among intellectuals in debunking naïve enthusiasm. What is needed, then, are accounts of empirical cases that are neither gullible nor cynical, but try to fully recognize the complexity and dilemmas as well as the real potentials of practical efforts at social empowerment. – Erik Olin Wright, *Envisioning Real Utopias* (2010, p. 151)

In a powerful passage, one of the world's leading literary critics in the past century, Edward W. Said wrote that “[t]he intellectual's representations—what he or she represents and how those ideas are represented to an audience—are always tied to and ought to remain an organic part of an ongoing experience in society: of the poor, the disadvantaged, the voiceless, the unrepresented, the powerless.” (1996, p. 113). But only a few embrace and sustain this commitment with the goodwill that Erik Olin Wright brought to his work and life.

Wright was a distinguished sociologist and, from 2011 to 2012, president of the American Sociological Association. He died on January 23, 2019, after 9 months of fighting acute myeloid leukemia. Born into a family of academics in California and raised in Kansas, Wright studied social science and history at Harvard and Oxford before starting a doctoral program in sociology at the University of California, Berkeley in 1971. Upon defending his dissertation, he was hired in the sociology department at the University of Wisconsin-Madison in 1976, where he stayed until his death. Leaving behind a tremendous oeuvre spanning more than 40 years, Wright generated a vast array of innovative research across an exceptionally wide array of subfields including social stratification, ethnography, political sociology, economic sociology, and sociology of gender. He will be remembered as the most influential theorist of class within the Marxist tradition in the second half of the twentieth century.

Since the early 1990s, Wright began a major research project entitled “The Real Utopias,” which at its heart, explores a wide range of proposals and models for radical and emancipatory social change. The central aim of the project is an attempt at bringing forth and sustaining serious debates around radical alternatives to existing structures of inequality, domination, and privilege. The objective, then, is to call forth specific, *workable* proposals to fundamentally redesign extant social institutions such that it yields

positive effects on human flourishing. This is inspired by Wright's commitment to a fundamental proposition in Marxist social science that "take [s] the intellectual from relatively discrete questions of interpretation to much more significant ones of social transformation" (Said 1996, p. 110). It is in this spirit that Wright started the project in order to design institutions and blueprints for a just social order – a task that Karl Marx himself forswore (Movahed 2021).

Utopias Versus *Real Utopias*

Prior to examining The Real Utopias Project in detail, an important distinction must be made between "utopia" and the oxymoron "Real Utopia." In strictly literal sense, utopia means "nowhere" (Wright 2012, p. 38). It is a fantasy world where ideals of a just and good society are fully realized; a place in the "imagination of peace and harmony, of flourishing lives and happiness." It "reflects the human longing for escape from the oppressions, disappointments, and harsh realities of the real social world" for one free of these maladies (Wright 2012, p. 38). *Real Utopias*, however, as Wright coined the term are much more than just passive dreams. It is a visionary and realistic attempt to "elaborate, clear-headed, rigorous, and viable alternatives to existing social institutions that both embody our deepest aspirations for human flourishing and take seriously the problem of practical design" (Wright 2012, p. 37). Hence, exploring real utopias necessarily suggests developing a sociology of the possible, and not just the observed. This is, as Wright recognized, is a delicate research problem, because discussions of possibilities (and impossibilities) – and not just observing variations in the world – always "involve more speculative and contentious claims (Wright 2010, 2012, p. 37)." The task of a sociology of the real utopias, then, is to open up a whole arena of social-analytical research "that enable us to make empirically and theoretically sound arguments about emancipatory possibilities" (Wright 2012, p. 37).

When it comes to understanding what is and what is not a real utopia, it is important to underscore the difference between *ameliorative* from *emancipatory* reforms. Ameliorative reforms such as welfare programs, unemployment insurance, maternity leave and the like are crucial because they provide some form of material relief to those who often need them (Calnitsky 2017). These forms of ameliorative reforms are ubiquitous across states in one way or another. Emancipatory reforms, however, not only contain ameliorative effect but also push us closer to the broader moral and utopian vision. They often carry a liberating effect by tipping the balance of power in favor of the powerless, the poor, the disadvantaged, and the voiceless. Hence, the real utopias are both "real" (i.e., viable, desirable, sustainable) and "utopian" (i.e., they go far beyond the normative visions of reforms that we have thus far experienced). Wright coined the term "Real Utopias" deliberately to indicate that strategies for transforming capitalism to a democratic socialism can be found in the nooks and crannies of actually existing capitalism. That is to say, we need to look for extant institutions that do not follow capitalist principles even as they operate within—or on the fringes of—the capitalist system.

Seeking to explore a wide range of realistic and achievable proposals for social and economic change presume identifying a set of immediate tasks. The exploration of real utopias is therefore an integral part of a broad agenda of an emancipatory social science and includes the following tasks: (1) identifying the *moral principles* for judging the effects of social institutions; (2) Using these moral principles as the standards for *diagnosis and critique* of existing institutions; (3) Developing an account of *viable alternatives* to the response to the critique; (4) Proposing a *theory of transformation* for realizing those alternatives (Wright 2010, 2012, p. 3). The first two tasks inform our perspective as to what kind of world do we want and what is wrong with the world in which we live; the third encourages us to think innovatively about

alternative ways of designing social blueprints; and the fourth helps us think about strategies of how to transform the existing structures (Wright 2012, p. 3).

Moral Principals

What are the moral principles that animate the real utopias? Wright identified three key principles that drive intellectual efforts to envision real utopias. Those include: equality, democracy, and sustainability (Wright 2010). It has now become obvious that capitalism impedes all of these ideals. Under capitalism, decisions and their implementation often lead to a significant degree of economic and social inequality (of income, wealth, power and life chances) that is hardly acceptable in a democracy built on principles based on equal rights and opportunities. As Wright argued, in a truly just society, “all people would have broadly equal access to the social and material conditions necessary for living a flourishing life” and in a “fully democratic society, all people would have broadly equal access to the necessary means to participate meaningfully in decisions about things that affect their lives” (Wright 2012, p. 3).

Developing an account of alternatives both for specific institutions and for macro-structures of society lies at the core of the Real Utopias Project. Alternatives can be evaluated in terms of three specific criteria: desirability, their viability, and their achievability (Wright 2010, pp. 18–23). If only the first of these three criteria is met and viability or achievability are ignored, then only a plain utopia is envisioned – not a real utopia. Envisioning real utopias therefore requires pragmatic undertaking, such that ideas are constantly examined and tested against the criteria highlighted above. However, the question that arises is that what are the notable example of real utopias that operate within capitalism through they do not follow capitalist logic? In what follows, I will briefly discuss the notable examples of real utopias. This list is not, by any means, exhaustive. For more detailed discussion of extant

examples of real utopias, see chapters 5, 6, and 7 of *Envisioning Real Utopias* (Wright 2010).

Notable Examples of Real Utopias

Unconditional basic income (UBI). It is a proposal to give every legal resident of a nation an income sufficient to live above the poverty line without any employment requirement – or any other conditions for that matter (Wright 2011, p. 41). UBI is a fundamental transformation of the income distribution system across societies, one that “has potentially profound ramifications for the realization of democratic egalitarian values” (Wright 2011, p. 41). It is one of the most liberating real utopias because it takes freedom to a different level. As Wright insisted, “for freedom to be meaningful you have to be able to make choices and above all, you have to be able to say no to things that are harmful to you. And that’s what an unconditional basic income does. It enables people to say no to bad employment” (Tunghai University, Memorial for Erik Wright, 2019, p. 1). Wright thus underscored the importance of UBI for the power relations in the broader class structure of capitalist societies. According to both Marxian and Weberian class analysis, in a capitalist setting, workers are separated from their means of production and hence, from their means of subsistence because they must enter the labor market and seek employment in order to socially reproduce themselves. This dual separation provides the material basis for the fundamental power imbalance between capital and labor: for workers to live, they have to sell their labor power, which then means they are forced to accept terms of exchange and working conditions, however abysmal they may be. Wright emphasized that UBI would not only have ramifications for the power imbalances of capitalist class relations, but its effect is particularly salient for the low-skilled, low-wage earners. For union and non-union workers, it supplies them with “permanent strike fund” and much greater collective bargaining power (Wright 2004, p. 79).

Worker-Owned Cooperatives. Perhaps one of the oldest visions for an emancipatory alternative to capitalism is the worker-owned firm. Marx insisted that the secret origins of capitalism, as an economic system, lay in an initial accumulation of capital that rested upon dispossessing workers of their means of production and then employing them as wage-laborers in capitalist firms (Marx 1992[1867]). And indeed, the most straightforward way of remedying this dispossession of workers is through democratizing capitalist firms by ways of expanding worker-owned firms. To be sure, worker cooperatives do operate within capitalism though they are not the dominant form of industrial and firm organization within market economies. The world's largest federation of worker cooperatives, Mondragon Corporation, is in the Basque region of Spain and is a conglomerate of more than 100 separate worker cooperatives that produce a wide range of goods and services, including high-end refrigerators, auto parts, bicycles, industrial robots, and more (Wright 2012). There are many virtues to expanding worker cooperatives. First, in workers cooperatives, profits do not go to some distant investors, but instead go directly to the workers themselves. Capital, therefore, remains grounded in the local economy and builds community wealth. Second, when workers themselves are the owners, capital remains accountable to the local community of workers. If workers are the owners, they will not just “shut down” the company and move it to the Global South just because it is cheaper and more profitable to produce there. Instead, they would devise some kind of mechanisms for the firm to remain operative and remain in place. Third, the feeling that workers themselves own the firm often grant them meaning and job satisfaction (Rothschild-Whitt and Whitt 1986).

Legislature By Lot or Sortition. Presenting pathologies of electoral democracy, Wright argued that randomly selected citizen assembly is likely to deepen democracy (Wright 2019; Gastil and Wright 2018). A number of familiar problems plague democratic processes even in highly dynamic electoral democracies including, “campaign finance, candidate selection biases,

and problematic media coverage” (Gastil and Wright 2018, p. 305). Sortition, Wright argued, could eliminate or substantially mitigate the shortcomings of electoral and legislative processes. The most immediate effect of sortition is that it solves the problem of control by the monied interests over electoral processes such that it allows those to hold power who are most trustworthy to do so – because they do not seek it in the first place. Legislature by lot would therefore give members of every group equal opportunity to share power and would preclude the formation of self-serving political forces that are often completely divorced from their electorates.

Wright devoted a lifetime to social justice research and his Real Utopias Project was inspired by the ideals of emancipatory social science, emphasizing the urgent on the need to design institutions, to be a realist with imagination, and to remain patient but perseverant. If Gramsci is famous for saying that we need pessimism of the intellect but optimism of the will, Erik Olin Wright showed us that we also need some optimism of the intellect to sustain optimism of the will. He will always be with us.

Reality

Jack S. Crumley II

Department of Philosophy, University of San Diego, San Diego, CA, USA

Abstract

Metaphysics aims at providing an account of the nature of ultimate reality. An enduring theme is the contrast between appearance and reality. Although differences exist, it is possible to see various theories as falling within a relatively small number of categories. The following provides an overview, beginning with a commonsense view. Naturalism is today widely held, with its roots in antiquity. This view, however, has from the beginning continued to be subject to doubts, especially concerning the nature of the mind or consciousness. A particularly bold view holds that reality is one, despite the seeming existence of or appearance of many individuals; two versions are presented – Spinoza’s substance view and Hegel’s absolute idealism. Hegel’s view is introduced through Kant’s transcendental idealism. The chapter concludes, with a consideration of the nature of three types of objects, the nature and existence of universals, which of course stretches back to Plato; possible worlds, whose existence and nature have been an especially prominent subject since the last decades of the twentieth century; and impossibilia or Meinongianism.

Reality as the World of Common Sense

Our experience of the world reveals (or at least seems to) a plurality of distinct objects or individuals. These objects are located in a real time and space, and they have a wide range of properties. We know of some of these properties by means of the senses, those such as color, sound, feel, taste, and fragrance. But some of the properties we attribute to these objects we learn from “experts,” often scientists. Thus, we learn from experts that the sun does not drop below the ocean horizon in the evening, and it is much, much bigger than the cloud that just hid it from view or that a table is constituted by, or is here in virtue of, protons, neutrons, and electrons and apparently even smaller things yet. And here we encounter the distinction between *reality* and *appearance*. Things may seem or appear one way but, in reality, is something very different. The table seems solid with no “gaps.” A very complex physical theory says otherwise. Indeed, the title of a recent book by a well-known physicist is *Reality Is Not What It Seems* (Rovelli 2017).

Moreover, the reality of common sense is a world in which these objects continue through time and that, in some unexplained sense, they are the same as they were before – that pup asleep in his favorite afternoon spot is the same pup that I left this morning. In addition to their properties, these objects have a variety of relations to one another: being to the left of, sitting on top of, belonging to, and being a part of. Perhaps the most important relation is that of cause and effect. This flame causes the water to boil; that magnet holds this flashlight to the side of the car. Indeed, the world of common sense is a “causal world” – these ice cubes wouldn’t be here were it not for the “cold” of that freezer, and that little baby wouldn’t be here were it not for the...well, you know that story.

Common sense holds that reality comprises a world of distinct individuals that *are physical*. This commonsense reality also includes *sentient* or *conscious* “objects”; some of these are even *self-conscious* beings. In some sense, all of the animal kingdom is sentient or “aware” of features in the environment. Common sense tells us that

we are in a world with other *minded* persons. Those persons have thoughts, beliefs and desires, and hopes and wishes, and they experience various sensations and emotions. We acknowledge that many animals similarly experience sensations such as pain and at least some basic emotions such as fear. At times, these minds or these mental lives seem very different from the physical or material world. Some express doubt that science can tell us what love is, while others seem sure that one day that some science of the mind, such as neuroscience, will tell us exactly what it is for Amelia to love Jack. And similarly for all the other thoughts, emotions, and sensations.
